The NDEP believes use of outdated (historical) occurrence data collected from 2001 through 2005 would be inappropriate because the quality of source water from the Lower Colorado River System has improved as a result of several successful remediation projects in the Las Vegas Valley. This source water provides the water supply for a large portion of the US population (approximately 26 million US residents) and for a large amount of irrigated vegetable crops. The current perchlorate concentrations in the Lower Colorado River System are significantly lower than the concentrations present when the occurrence data were collected (2001 - 2005). The NDEP believes that collection of new occurrence data would permit a more accurate assessment of the exposure scenario and lead to a conclusion that regulation of perchlorate under the Safe Drinking Water Act (SDWA) does not present a meaningful opportunity for health risk reduction for persons served by public water systems or through ingestion of the referenced irrigated crops. The following summary of perchlorate remediation efforts within the Las Vegas Valley and corresponding water quality improvements within the Lower Colorado River system are provided to support this comment.

Response: EPA disagrees with the statement that UCMR 1 data is obsolete. The UCMR 1 includes sample results reported by 3,865 public water systems between 2001 and 2005. This is the best available data collected in accordance with accepted methods on perchlorate. EPA recognizes that changes in perchlorate levels may have occurred in water systems since the UCMR samples were collected. However, EPA does not believe that the regulatory determination should be further delayed when we have a robust data set that can be used to evaluate occurrence. EPA plans to further analyze available perchlorate data in developing a proposed drinking water regulation.

EPA Comment Code: 3100 UCMR 1 occurrence analysis

Comment: First, Phillips and Chambless,(see reference 1 electronic attachment - "Phillips compliance data variability.pdf") [see PDF of docket ID EPA-HQ- OW-2007-0068-0163] evaluated compliance data for several contaminants obtained from a cross section of state regulatory agencies and found consistently large variability in the means of quarterly samples taken for compliance purposes. This variability, expressed as the standard error of the mean divided by the mean, is significant enough (100% or more in many cases) to call into question the validity of decisions made based on these data. There is no reason to assume that the quality of the occurrence data from the UCMR effort would be any better than the quality of these compliance data, and NRWA strongly recommends that EPA resolve this quality issue before trying to make CCL2 regulatory decisions that are based on rather precise calculations of occurrence levels times the number of persons exposed.

Response: EPA respectfully disagrees with NRWA on the assertion that the validity of occurrence data from UCMR be compromised based upon an analysis of variability in compliance monitoring data collected by public water systems. UCMR has gone under rigorous QA/QC measures to ensure that data variability is at a minimum. A detailed description of UCMR monitoring can be found in the Federal Register under docket number EPA–HQ–OW–2007–0068. The title of the reference that describes UCMR is "The Analysis Of Occurrence Data From The First Unregulated Contaminant Monitoring Regulation (UCMR 1) In Support Of Regulatory Determinations For The Second Drinking Water Contaminant Candidate List".

EPA Comment ID: 20656
EPA Comment Code: 3100

Comment: Fifth, EPA has extensive monitoring data from public water systems on perchlorate occurrence in drinking water. While your November 5th letter [See PDF Docket ID EPA-HQ-OW-2008-0692-1749] states perchlorate has "wide occurrence," EPA's UCMR 1 data suggests that drinking water perchlorate occurrence is much less frequent that other compounds (sodium, manganese, sulfate, and boron) for which EPA has determined Federal drinking water standards are not necessary. The monitoring data also show that, for an overwhelming majority of the US population served by public water systems, exposure to perchlorate in drinking water is at a concentration much less than EPA's calculated HRL of 15 ppb. In fact, based on UCMR1, only 1.8% of public water systems had levels of perchlorate that were above the minimum reporting limit of 4 ppb.[FN8: US EPA, Unregulated Contaminant Monitoring Regulation 1 List 1 Assessment

Monitoring, 1999.] Although unpublished, the EPA's merger of the NHANES-UCMR1 datasets study has been peer-reviewed.

Response: Administrator Stephen Johnson replied to the SAB on January 9, 2009. The letter is available in EPA's docket ID No. EPA-HQ-OW-2009-0297 for this notice. EPA disagrees that only 1.8% of public water systems had levels of perchlorate that were above the minimum reporting limit. In the October 2008 FR notice, EPA presented information on the drinking water occurrence of perchlorate. The data source was EPA's UCMR 1 and the samples were collected between 2001 and 2005. A total of 34,331 samples were collected from 3,865 public water systems. EPA found that 4.1% of the systems (160 out of 3,865 systems) reported perchlorate at, or above, the MRL of 4ug/L.

EPA Comment Code: 3100

Comment: 10. Also regarding UCMR sampling, your letter questions the UCMR sampling because it focused only on large PWSs and does not account for exposure from "local hot spots" due to blasting, fireworks, and industrial and military releases.

The UCMR is the most complete source of information on contaminant occurrence in the nation's drinking water sources. The process for collecting data on unregulated contaminants in large as well as small water systems has been well established and relied upon by EPA for regulatory determinations from both the Contaminant Candidate List (CCL) 1 (issued July 2003) and CCL 2 (issued July 2008). Additionally the National Rural Water Association, a non-profit federation of state rural water associations (and has the largest utility membership) expressed support for EPA's preliminary determination, stating "the Agency has relied on sound science" in making its decision."[FN9: National Rural Water Association, Drinking Water Preliminary Regulatory Determination on Perchlorate (Docket Number: EPA-HQ-OW-2008-0692), Nov. 10, 2008.]

Comment: Public supplies in Connecticut were tested for perchlorate as part of the 2001 Unregulated Contaminant Monitoring Rule (UCMR) round of testing. There were no detections in those systems at that time. However, that is a snapshot and not nearly the complete and ongoing surveillance that a federal MCL would provide. We note that the parallel UCMR testing in Massachusetts found very few detections of perchlorate and yet additional testing by the State of Massachusetts found substantial public water contamination on a site-related basis. Additional testing in Connecticut is warranted given the changing use pattern of perchlorate in blasting materials, fireworks and other applications.

EPA Comment Code: 3100

Comment: It is important for EPA to properly characterize its estimates of the potential population exposed to perchlorate. Perchlorate cleanup along the Colorado River has been very successful in recent years, and this represents the water supply for 26 million people in the Southwest. Perchlorate was detected in the Las Vegas Wash in 1997. The contamination was due to past disposal practices at the perchlorate manufacturing sites in the Las Vegas valley. Due to efforts of the manufacturers, Tronox LLC (Kerr-McGee Chemical LLC) and American Pacific Corporation, working with the Nevada Division of Environmental Protection, perchlorate concentrations entering Lake Mead and the lower Colorado River System have decreased dramatically. The perchlorate load entering Lake Mead in 1998 was 1013 lbs/day; it has been currently reduced to 61 lbs/day.

Perchlorate concentrations have also decreased dramatically in the drinking water since 1998 throughout the lower Colorado River system. The average perchlorate concentration reported by the Authority and the City of Henderson for the Unregulated Contaminate Monitoring Rule (UCMR) averaged 9.6ug/L and 2.9 ug/L, respectively. Currently, the perchlorate concentration in the Authority and the City of Henderson's drinking water is an average of 2.1ug/L. Drinking water providers along the lower Colorado River have reported similar decreases in perchlorate concentrations. The data collected for the UCMR may not reflect current perchlorate exposure for the Southwest. The average perchlorate concentration at Whitsett Reservoir for the last two years is 1.6 ug/L. This is the Colorado River source water for the Metropolitan Water District of Southern California and the Central Arizona Project. California and Arizona blend with instate waters which result in a lower concentration. Three states have adopted perchlorate standards of 6 ug/L or less, which requires the water wells to be shut down if above the state limit. The exposure to perchlorate has been reduced significantly in the Southwest.

Comment: Consequently, the NDEP believes use of outdated (historical) occurrence data collected from 2001 through 2005 would be inappropriate because the source water (Lower Colorado River System) for a large portion of the US population and for a large amount of irrigated vegetable crops has substantially improved as a result of several successful remediation projects in the Las Vegas Valley. The current perchlorate concentrations are significantly lower than the historical concentrations when the occurrence data were collected (2001 - 2005). Moreover, current concentrations of perchlorate in the Lower Colorado River System are less than health-protective levels for the approximately 26 million US residents who use this water for drinking water and numerous agricultural operations for irrigating crops. The NDEP believes that collection of new occurrence data would provide for a more accurate assessment of the exposure scenario applicable to this large segment of the US population, and lead to a conclusion that regulation of perchlorate under the SDWA does not present a meaningful opportunity for health risk reduction for persons served by public water systems or consuming the above-referenced irrigated crops.

Comment: Current National Exposure to Drinking Water Perchlorate

AWWA believes that the population exposed to perchlorate that was indicated by EPA's UCMR1 data is no longer valid. In an informal survey conducted by AWWA, we found that many sources that had detected perchlorate from UCMR1 monitoring are either no longer being used or are being treated per the requirements of maximum contaminant levels (MCL's) established in California and Massachusetts. Additionally, successful treatment of the perchlorate source to Colorado River contamination has lowered concentrations to below 4 ug/L. AWWA believes that EPA would be well served to work with state primacy agencies to evaluate the 160 water systems with perchlorate

detections from UCMR1 to determine the actual national population currently exposed to perchlorate above 4 ug/L. AWWA believes this information will further help inform EPA as to whether there is a meaningful opportunity for health risk reduction by regulating perchlorate.

Response: EPA acknowledges that there may be changes (increasing or decreasing) in the levels of perchlorate in public water systems since the UCMR data were collected from 2001 to 2005. EPA believes the UCMR data are best available data collected in accordance with accepted methods on the frequency and level of occurrence in drinking water. Therefore EPA is basing its occurrence evaluation on these collected data for the regulatory determination and will further evaluate perchlorate occurrence as part of the proposed rulemaking.

Comment: 3. Use of data on perchlorate occurrence in drinking water: The occurrence analysis presented in the Notice relies on data that are nearly a decade old and it assumes exposure to maximum concentrations detected anywhere within a public water system (PWS), even in untreated source water. Therefore, the analysis most likely overestimates concentrations of perchlorate in drinking water. Additionally, the Notice's estimates of populations exposed to perchlorate are overstated because it assumes the entire population served by a PWS is exposed to the maximum concentration, even if the detection was in untreated source water, and it overlooks the steps that have been taken- particularly in California, Massachusetts and New Jersey-that substantially reduce the national population that may be exposed to environmental levels of perchlorate. The process the Notice followed to develop the estimated populations is not transparent, and as a result, it is not possible to independently calculate the estimated values in the Notice based on the information given. Independent calculations resulted in estimated population sizes that are about half of the Notice's estimates, even when conservative assumptions were used. EPA should use more current data to estimate occurrence as levels in drinking water have decreased since UCMR1 monitoring.

Response: See response to comment ID 28856 under comment code 3100 in regards to changes in the levels of perchlorate occurrence. With respect to EPA's evaluation of populations exposed to perchlorate, the Agency has presented analyses as part of its October 2008 Federal Register Notice, August 2009 Federal Register Notice, and the Final Federal Register Notice that explains EPA's estimation of populations potentially exposed to perchlorate. Using the UCMR 1 data, EPA took into account the potential for overestimating populations exposed to perchlorate using UCMR 1 monitoring data in which one can assume that the entire population served by a PWS is exposed to the maximum concentration from a single detection. Therefore, to respond to this concern, EPA also developed a central value estimate by assuming the population was equally distributed among all entry points and added only the proportion of the total population served by those entry points in a PWS that had at least one sample with perchlorate concentrations greater than the HRL being evaluated.

Comment: C. Use of Data on Perchlorate Occurrence in Drinking Water

To estimate how many people potentially could be exposed to perchlorate in drinking water, EPA used data from its first cycle of the UCMR1 (http://www.epa.gov/safewater/ucmr/ucmr1/index.html). The Notice presents the resulting population estimates in Table 3. The Agency estimated the size of the population exposed to perchlorate at different threshold levels (4 ug/L or higher, 5 ug/L or higher, etc.) by assuming that the entire population served by a public water system (PWS) is exposed to perchlorate at concentrations above a threshold level if at least one sample collected in the PWS contained perchlorate at or above the threshold level (even if all other samples are lower, or nondetect). Based on this assumption, the Notice reports an estimate of 16.6 million (M) people exposed to perchlorate at concentrations above the method reporting limit (MRL) of 4 ug/L. In addition, the Agency developed an alternative assessment by assuming that populations served by PWSs are equally distributed among entry points to the PWS and that only those portions of the population served by entry points with reported concentrations above the threshold are exposed. Based on this assumption, the Notice reports an estimate of 5.1M people exposed to perchlorate at concentrations above the MRL of 4 ug/L.

The Notice asks for comment on three general questions regarding the use of occurrence data to estimate exposure to perchlorate. Responses to these questions, based on the best available scientific information, follow.

Response: No response necessary to this summary of EPA information.

EPA Comment Code: 3100

Comment: Scientific and statistical concerns with the Notice's use of the UCMR1 data set include the following:

* UCMR1 covers the years 2001 to 2005; some of these data are nearly a decade old. Data collected during this time overestimate current concentrations of perchlorate in drinking water. Guidelines EPA has established since 1992, including interim guidance for remediation and water exposure levels, and remediation of contaminated sites by responsible parties, have resulted in reductions in perchlorate levels in ground and surface water. For example, public information shows that annual average concentrations of perchlorate at the Las Vegas drinking water intake in Lake Mead declined almost 60% between 2000 and 2004 (from 13.1 ppb to 5.6 ppb), and the annual average concentrations in the Metropolitan Water District Colorado River Aqueduct intake at Lake Havasu on the Lower Colorado River declined about 50% between 2000 and 2004 (from 6.4 ppb to less than 4 ppb), and in 2004 nine of the twelve monthly samples were at levels too low to detect (i.e., below 4 ppb) (http://www.epa.gov/region/toxic/perchlorate/per_nv.html). The Colorado River

supplies water for agriculture in Arizona and California as well as drinking water for Southern California.

* Environmental exposure levels of perchlorate are declining. Although not an occurrence study, a recent study reports that urinary concentration of perchlorate is lower in NHANES 2003-2004 participants compared to NHANES 2001-2002[FN15: NHANES 2001-2002 is the basis for the study by Blount et al. (2006). See following section for the full discussion on Blount et al. (2006).] suggesting population exposure was lower during 2003-2004 (Mendez et al., 2009).

* Examination of the UCMR1 data set demonstrates that several major U.S. cities did not detect perchlorate in their drinking water. These cities are large metropolitan areas with corresponding large populations and include Washington DC, New York City, Newark, Baltimore, Philadelphia, Pittsburgh, Minneapolis/ St. Paul, Chicago, Milwaukee, Detroit, Cleveland, Indianapolis, Memphis, Nashville, Atlanta, St. Louis, San Francisco, Seattle, and Portland. Perchlorate is not ubiquitous in drinking water, but areas of detection appear to be regionalized. This does not diminish the importance of perchlorate where it has been detected at levels above the MRL (4 ug/L). States where significant perchlorate is present, e.g., California, have either promulgated drinking water standards or adopted EPA interim guidance. As a result, the trend of occurrence is toward lower water concentrations.

* The population estimates presented in Table 3 of the Notice could not be validated. The Notice does not present all of the assumptions used to calculate population sizes. When extremely conservative assumptions are made, calculated population sizes are still much lower than EPA's estimates. For example, if it is assumed that the entire population served by a PWS is exposed to perchlorate at levels above the MRL when at least one sample collected in the PWS contained perchlorate at or above the MRL (even if all other samples did not detect perchlorate) and that the size of the population is the maximum associated with the category assigned to a given PWS (i.e., very small, small, medium, large, very large), the computed maximum exposed population size is approximately 10.5M-this is approximately 60% of EPA's maximum estimate of 16.6M. This lower estimate is still extremely conservative and unlikely to accurately represent the size of the exposed population. The entire population served by the PWS is not likely to be served water from the entry point that had the highest reported concentration, and actual population sizes for each PWS are likely to be distributed across the range of population sizes associated with a given population category. Alternatively, if it is assumed that the population served by a PWS is equally distributed among entry points to the PWS and the total exposed population is computed based only on those entry points where perchlorate was detected above the MRL (i.e., in a manner consistent with the last column of EPA's Table 3), the estimated population size is about half of EPA's 5.1M estimate.

* It appears that EPA included monitoring data for untreated source water in its exposure estimates. Based on the data retrieved from EPA's UCMR1 website, the UCMR1 data includes a total of 34,728 analyses for perchlorate (EPA reports 34,221 analyses), with 647 detections of perchlorate at or above the MRL (EPA reports 637 detects). These detections include 288 detections in source water (out of 10,684 samples, or a frequency of detection of 2.7%) and 348 detections in entry point water (out of 23,319 samples, or 1.5%) (perchlorate was not detected in any samples from the midpoint of distribution systems (n = 16), the point of maximum retention (n = 19), or the location in distribution systems where disinfectant residual is lowest (n = 6); perchlorate was detected in 11 of 684 samples from "unknown" locations). Thus, it is questionable as to whether the number of

people presented in the Notice is likely to drink untreated source water from PWSs, and data from drinking water entry points indicates that concentrations at the entry points are generally lower.

These observations indicate that using the UCMR1 database to extrapolate exposures to concentrations below the MRL would be inappropriate, as it would produce highly inaccurate estimates.

Response: Regarding the comment that UCMR data overestimates current concentrations of perchlorate in drinking water, see response to comment ID 28856 under comment code 3100.

Regarding the comment that perchlorate is not ubiquitous in drinking water but areas of detection appear to be regionalized, UCMR data is the most extensive nationally representative occurrence data for perchlorate in public water systems; therefore, EPA analyzed this data and additional occurrence data in making a regulatory determination for perchlorate as required by Congress. See SDWA Section 1445(g).

Regarding validation of population estimates, see responses to comment IDs 28856 and 28870 under comment code 3100. Also, see "The Analysis Of Occurrence Data from The First Unregulated Contaminant Monitoring Regulation (UCMR 1) In Support Of Regulatory Determinations For The Second Drinking Water Contaminant Candidate List" for a description of how the UCMR 1 population analysis was conducted.

EPA disagrees with the commenter that approximately half of perchlorate water samples in the UCMR 1 database are from untreated source waters. The data EPA used to evaluate perchlorate occurrence from UCMR 1 was only taken from finished water. EPA did allow monitoring at source water sampling points; however, if perchlorate was detected in a source water sample, the UCMR 1 required that follow-up samples be collected at the entry point to the distribution system and follow the monitoring frequency specified in the rule for the contaminant and water source type. A detailed description of UCMR monitoring can be found in the Federal Register under docket number EPA–HQ–OW–2007–0068. The title of the reference that describes UCMR is "The Analysis Of Occurrence Data From The First Unregulated Contaminant Monitoring Regulation (UCMR 1) In Support Of Regulatory Determinations For The Second Drinking Water Contaminant Candidate List."

EPA Comment ID: 28904
EPA Comment Code: 3100

Comment: 3. EPA's proposed analysis of occurrence data is concerning in that the estimated population sizes in the Notice could not be reproduced, the data from UCMR1 are not current and likely overestimate current exposures, and the highest concentration detected anywhere in a PWS was used to estimate exposures for all people served by the PWS, even if the sample was collected from untreated source water or all other samples were nondetects. Altogether, these assumptions

produce an inaccurate and overly conservative estimate of potential human perchlorate exposures from drinking water.

Response: See response to comment IDs 28856 and 28870 under comment code 3100.

Commenter Name: Michael Girard
Commenter Organization: Perchlorate Study Group
EPA Document ID: EPA-HQ-OW-2008-0692-1855
EPA Comment ID: 29097
EPA Comment Code: 3100

Comment: EPA assumes that if the drinking water testing at the entry point reports at least one sample above the detection limit during the 2000-2005 UCMR sampling period, the entire population that draws drinking water from that intake is exposed. EPA then multiplies this estimate of the exposed population by an estimate of the proportion of the national population that is pregnant during any given year.

The major overestimate in EPA's calculation concerns the population exposed above the HRL. Under the UCMR regulation, public water systems were required to take multiple samples throughout the year at each sampling point. Large public water systems were required to monitor throughout a three-year period. Many of the sampling points only reported a single detection during the sampling period. Few systems reported perchlorate detections in every sample. Therefore, assuming the total population is exposed at any given time is a gross overestimate. A more likely estimate is the ratio of positive defects to total samples multiplied by the service population.

There are many reasons why a system may have intermittent or a single detection. At the beginning of the UCMR sampling period, laboratory experience with detecting perchlorate was evolving. There have been many anecdotal reports of false detections. Even where perchlorate was found in the drinking water, its occurrence may have been intermittent. Since perchlorate can be naturally formed and then fall to the earth in precipitation, it is likely that watershed concentrations ebb and flow with the natural water cycle.

EPA's estimate in the proposed determination also overestimates the likely number of individuals with drinking water concentrations above the HRL for several other reasons. First, EPA failed to remove individuals who primarily consume bottled water or have in-house treatment systems. EPA did exclude these individuals in its analysis of the UCMR/NHANES data sets.

Second, EPA did not account for system changes in response to the UCMR monitoring. Some states have enacted state-specific drinking water standards. Others have issued advisory levels. Public water systems have responded and have made changes to reduce perchlorate concentrations. These changes are exactly the responses the Safe Drinking Water Act encourages. By prompting local actions, drinking water issues are separated into the local and national concerns. EPA should properly account for these local actions in its population estimate so as to reinforce its finding that exposure does not occur with sufficient frequency to warrant national regulation.

More importantly, EPA should provide the public context for this exposure estimate. Even though there may be potentially exposed individuals above the HRL, the overwhelming scientific evidence

from clinical studies, environmental studies, and from PBPK modeling demonstrates that no one faces an appreciable risk of adverse effect from exposures at EPA's reference dose.

Response: EPA has used the best available data on the frequency and level of perchlorate occurrence in drinking water, the population exposed to perchlorate, and the levels of public health concern to determine that there is a meaningful opportunity for health risk reduction through a national primary drinking water regulation. EPA believes that this analysis is appropriate for making the determination to regulate perchlorate which will initiate a more rigorous health risk reduction, cost analysis, and other analyses required by the Safe Drinking Water Act for proposed drinking water standards. EPA believes that it is appropriate to consider the single highest value reported in a public water system and the highest level within a entry point into the system. While EPA does acknowledge that perchlorate concentrations may fluctuate over time, the duration of life stages where individuals are most sensitive to the effects of perchlorate exposure (i.e., pregnancy and infancy) are relatively short. Therefore EPA believes it is appropriate to use the single highest result from a quarterly or semi-annual sample to determine if these populations are exposed at levels of health concern.

EPA does not believe that multiplying the ratio of positive detects to total samples by the service population is appropriate because this approach would not account for the fact that during certain periods of time the whole population was potentially exposed to perchlorate in drinking water at levels of health concern. EPA does not believe that is appropriate to remove persons who use in house treatment or consume bottled water for these estimates of population potentially exposed. The bottled water consumption and in house treatment data were available for NHANES participants but are not collected or reported under the UCMR. EPA believes that a more rigorous evaluation of the variation in drinking water consumption can be made as part of the health risk reduction and cost analyses required under SDWA for proposed national primary drinking water regulations.

EPA does not believe that it is appropriate to adjust estimates of perchlorate occurrence from those measured under UCMR. EPA believes that the UCMR is the best available data on the frequency and level of perchlorate occurrence in public water systems nationally. EPA acknowledges that levels of perchlorate may have decreased in some public water systems as a result of state regulation or of water system decisions. However, those may also be instances in which levels of perchlorate may have increased due to new contamination. EPA further notes that public water systems would conduct monitoring under the national primary drinking water regulation we expect to promulgate. Systems which do not detect perchlorate at levels exceeding the MCL will not be required to take action to lower perchlorae levels. Therefore if systems have already taken actions to address perchlorate in their drinking water, these systems may not have to take any further steps to remove perchlorate .

Regarding the statement that no one faces an appreciable risk of adverse effects from exposures at EPA's reference dose, a recent study (Steinmaus et al., 2010) examining the perchlorate concentration in drinking water and its association with neonatal thyroid hormone levels in over 400,000 newborns, concluded that there is a statistically significant association with perchlorate exposure and increased neonatal thyroid hormone levels. This study has shown that, at environmental concentrations of perchlorate greater than 5 ug/L, the odds of elevation in thyroid stimulating hormone (TSH) levels at birth was significantly greater, when compared to hormone levels in newborns from communities unexposed to perchlorate. Steinmaus et al. (2010) grouped

geographic communities in California according to whether their respective estimated average perchlorate concentrations were either more or less than 5 ug/L, therefore, unexposed communities in this particular study were defined as having less than 5 ug/L drinking water perchlorate concentrations (representing an average estimate of perchlorate concentrations of the different water systems supplying a given community, and weighted by the number of water sources used by each system). Therefore, for the Steinmaus et al. (2010) study, this particular unexposed group includes communities with estimated average perchlorate concentrations of 5 µg/L or less, as well as all communities with no measurable environmental perchlorate concentrations. The U.S. EPA reference dose for perchlorate is 0.7 ug/kg/day. EPA has adopted the NRC's recommendations regarding the reference dose for perchlorate in its "Integrated Risk Information System" (IRIS) (USEPA 2005), resulting in an RfD of 0.7 ug/kg/day, which was derived by applying a 10-fold (10x) uncertainty factor to the NOEL of 7.0 ug/kg/day.

EPA Comment Code: 3120

Comment: The other concern is that, as noted earlier, without a federal MCL, detections of high level contamination (e.g., 1300 ug/L of perchlorate in a public water supply in Boxborough MA) will go undetected leading to high localized exposures. This high level of contamination would not have been detected without a state initiated testing program (MADEP, 2005). Given the unpredictable nature of these extreme concentrations, national monitoring is clearly needed.

The 2001 Unregulated Contaminant Monitoring Regulation (UCMR) for perchlorate focused upon larger public water supplies and is not indicative of the numbers of people exposed or extent of exceedances possible from localized hot spots due to contamination of water from blasting, fireworks or industrial/military releases.

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120. EPA intends to consider compliance monitoring requirements and request comment as part of the expected proposed national primary drinking water regulation for perchlorate. EPA disagrees with the statement that the UCMR is not indicative of the numbers of people exposed to perchlorate. Under UCMR 1, EPA collected samples from all the large PWS (3,865) and 800 small PWS which were a stratified random sample of public water systesms selected to represent drinking water occurrence nationally. EPA has determined that UCMR 1 is the best available scientific perchlorate occurrence data collected in accordance with acceptable analytical methods. EPA's determination is based upon the fact that UCMR1 is the most nationally representative study of the frequency and levels of perchlorate in drinking water systems.

Commenter Name: Ron Curry
Commenter Organization: New Mexico Environment Department
EPA Document ID: EPA-HQ-OW-2008-0692-1796
EPA Comment ID: 20932
EPA Comment Code: 3120

Comment: Because perchlorate is not currently regulated under the SDWA, data on perchlorate contamination in New Mexico public water systems is limited. Under the Unregulated Contaminant Monitoring Rule,[FN1: 40 C.F.R. [section] 141.40.] public water systems serving communities of greater than 10,000 persons were required to monitor for perchlorate for one year between 2001 and 2003. A "statistically representative" number of additional smaller systems were also required to monitor for perchlorate for one year during this time period. However, with few exceptions, that monitoring data does not appear to have been reported to the State of New Mexico. Therefore, the

Environment Department has only a very incomplete picture of perchlorate contamination in public water systems in the State.

Response: EPA has made the UCMR monitoring data publicly available. EPA has determined that this data is the best available data (collected in accordance with accepted methods) on the occurrence of perchlorate nationally.

EPA Comment Code: 3140 UCMR 1 entry-point-level estimation of perchlorate exposure

EPA Document ID: EPA-HQ-OW-2008-0692-1797
EPA Comment ID: 20952
EPA Comment Code: 3140

Comment: Perchlorate is Present at Sufficient Levels and Frequency to Constitute a Public Health Concern

EPA's determination of whether perchlorate is present at sufficient levels and frequency to constitute a public health concern begins with an analysis of occurrence and population estimates for perchlorate at various thresholds. Since the data on occurrence may not represent water samples delivered to the entire service population, EPA considers two values fore each threshold or cut-point considered (e.g., 4, 5, 7, 10, 12, 15, 17, 20 and 25 ug/L); the first value is the service population, and the second is an estimate below the service population, that is derived from the service population divided by the number of entry or sample points. The second value is in all cases substantially lower than that of the service population. To ensure the protection of public health, we recommend that the more conservative number - that of the entire service population - should be considered as the potentially impacted population.

Response: EPA has decided to regulate perchlorate in drinking water. See response to comment code 6120. In the Federal Register notice "Final Regulatory Determination on Perchlorate" EPA considers a range of estimates of the population served by PWSs that had at least one sample with perchlorate concentrations greater than the potential HRLs. The population range represents both a high end estimate, as well as a central value estimate. The high end estimate is derived by adding the entire system population of all PWSs in which at least one sample was found to contain perchlorate above thethreshold. EPA considers this a high end estimate because it is based on the assumption that the entire system population is served water from the entry point that had the highest reported perchlorate concentration. In fact, many PWSs have multiple entry points into which treated water is pumped for distribution to their consumers. For the PWSs with multiple entry points, it is unlikely that the entire service population receives water from the one entry point with the highest single concentration. Therefore, EPA also provides a central value estimate of the population served water with perchlorate above a threshold. EPA developed this central value estimate by assuming the population was equally distributed among all entry points and added only the proportion of the total population served by those entry points in a PWS that had at least one sample with perchlorate concentrations greater than the threshold. EPA considered both the high end estimate and central value estimate in making this final regulatory determination. The Agency considered the central value estimate as well because this is likely a better estimate of the population exposed to perchlorate at levels of public health concern.

EPA Document ID: EPA-HQ-OW-2009-0297-0495
EPA Comment ID: 28866
EPA Comment Code: 3140

Comment: We also wish to note that the population estimates in column 5 of Table three would be likely to underestimate those exposed in MA, and quite likely other states, due to mixing of supplies from multiple entry points.

Response: Please see the response to comment ID 20952 in comment code 3140. In addition to the central value population estimates provided in the "Final Regulatory Determination on Perchlorate" notice, EPA also considered estimates of the total population served by drinking water systems in which at least one sample was found to contain perchlorate above the threshold (i.e., the high end estimate) to account for the mixing of supplies from multiple entry points to the distribution system.

Commenter Name: Anila Jacob
Commenter Organization: Environmental Working Group (EWG)

EPA Document ID: EPA-HQ-OW-2009-0297-0499
EPA Comment ID: 28933
EPA Comment Code: 3140

Comment: Occurrence analysis: EPA's occurrence analysis grossly underestimates the number of people at risk from perchlorate because of an inappropriately high detection and reporting threshold of four ppb.

In table 3 of the notice in the federal register, the Agency lists the occurrence and population estimates for perchlorate above a number of thresholds, starting at 4ppb. This data is derived from the Agency's Unregulated Contaminant Monitoring Rule (UCMR) 1; the Agency estimates that a total of 16.6 million people in the United States are served by public water systems with at least 1 detection of perchlorate at > 4 ppb.

In table 2 of the federal register, the agency finds that HRLs as low as 1 are necessary to prevent children ages two and younger who have higher water ingestion rates and cumulative perchlorate exposures that can easily exceed the RfD. In addition, as mentioned above, the degree of perchlorate contamination of some powdered infant formulas is so high than an HRL as low as 0 is justified for infants six months and younger. Therefore, the finding of perchlorate in drinking water at any level presents risks to vulnerable populations and until the minimum reporting level (MRL) is decreased to reflect this, the agency's numbers are an underestimate.

Response: EPA acknowledges that there are newer and more sensitive analytical methods that are now available that would permit perchlorate analysis with reporting limits below 4 ug/L (the MRL for perchlorate under the UCMR 1 was 4 ug/L); however, the 1996 amendments to the Safe Drinking Water Act require the Agency to consider the best available, peer reviewed science when developing drinking water standards. In applying these principles, "best available" usually refers to the availability at the time an assessment is made. EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). As part of the rulemaking process, EPA plans further analyze perchlorate occurrence data to estimate the additional number of PWSs and entry points and the population served at levels of public health concern.

EPA Comment Code: 3150 Potential use of a Bayesian model to estimate number of PWSs and population served at a range of thresholds

Response to Code 3150: EPA continues to evaluate the utility of the Bayesian model(s) in the development of a NPDWR for perchlorate. EPA plans to be transparent in explaining the analysis and any assumptions made when presenting the analysis in connection with the proposed NPDWR. EPA does not intend to distinguish the source of perchlorate in drinking water but does intend to assess the number of water systems impacted by a potential regulation.

Commenter Organization: Association of State Drinking Water Administrators
EPA Document ID: EPA-HQ-OW-2009-0297-0525
EPA Comment ID: 28500
EPA Comment Code: 3150

Comment: a. EPA requests comment on the potential use of a Bayesian model to estimate the number of public water systems, and populations served by such systems, with at least one estimated sample detection greater than 1, 2, 3, 4, 5, 7, 10, 12, 15, 17, 20, and 25 [mu]g/L.

ASDWA feels that it is necessary to do further modeling to estimate perchlorate levels below the analytical method MRL used in the UCMR monitoring and the Baysean modeling approach discussed in the notice strikes us as a reasonable one. Data from Massachusetts with a lower detection limit can be used to refine and validate the modeling so that more precise estimates can be made of occurrence at these very low levels. EPA should also include any new data received as a result of this notice in its analysis.

Response: See response to comment code 3150. EPA has reviewed other occurrence data.

EPA Comment Code: 3150

Comment: September 17, 2009

Water Docket Environmental Protection Agency Mailcode: 2822T 1200 Pennsylvania Ave., NW Washington, DC 20460

SUBJECT: Comments on the Drinking Water: Perchlorate Supplemental request for Comments Docket ID No. EPA-HQ-OW-2009-0297

The Southern Nevada Water Authority (Authority) appreciates the opportunity to comment on the preliminary regulatory determination for perchlorate as listed in the August 19, 2009 Federal Register (74 FR 41883). The Authority is a cooperative agency formed in 1991 to address Southern

Nevada's unique water needs on a regional basis. Officials of the Authority are charged with managing the region's water resources and providing for approximately 2 million area residents' present and future water needs. The Authority is governed by a seven- member board comprised of representatives from each of its member agencies, which include the cities of Boulder City, Henderson, Las Vegas and North Las Vegas, as well as agencies serving customers in unincorporated Clark County and the town of Laughlin.

The Authority's responsibilities include managing water supplies available to Southern Nevada and regional conservation programs as well as building and operating regional facilities to provide a reliable drinking water delivery system to all member agencies.

Interpretation of the Physiologically-Based Pharmacokinetic (PBPK) Modeling

The Authority strongly encourages the use of sound science in the consideration of federal regulation of perchlorate. While modeling such as the PBPK and Bayesian hierarchical models suggested in the noted Federal Register (FR) are of value when empirical data are unavailable, the use of these models for the elucidation of health reference levels and national occurrence, respectively, are not necessary as sufficient data already exist.

Response: EPA continues to evaluate the utility of the Bayesian model(s) in the development of a NPDWR for perchlorate. EPA plans to be transparent in explaining the analysis and any assumptions made when presenting the analysis in connection with the proposed NPDWR. See response to comment code 3150.

Commenter Name: Kay Brothers

EPA Comment Code: 3150

Comment: Occurrence Analysis

The Authority also does not support the use of Bayesian hierarchical models to extrapolate the Massachusetts' occurrence data to develop a portrait of sub-4 ug/L perchlorate occurrence nationwide. While we understand the great value of Bayesian models, we see no reason for applying these models considering that the preponderance of data suggest that perchlorate is not relevant to human health even at 4 ug/L and considering the inappropriateness of applying a relative source contribution (RSC) factor to perchlorate when using the Greer study or others where dietary contributions have already been accounted. Moreover, other studies have already shown that perchlorate is ubiquitous in the environment at concentrations above approximately 0.050 ng/L (Rickman 2003; Richardson 2004; Snyder, Vanderford et al. 2005), owing largely to the atmospheric formation and subsequent deposition of perchlorate in rain (Dasgupta, Martinelango et al. 2005; Rajagopalan, Anderson et al. 2006).

Response: See response to comment code 3150. EPA disagrees with the commenter's view that perchlorate is not relevant to human health even at 4 ug/L and that applying an RSC factor to perchlorate is inappropriate. See response to comment code 5220 for an explanation of EPA's

rationale in concluding that perchlorate is relevant to human health at or below 4 ug/L. See response to comment code 5210 for an explanation of EPA's use of an RSC.

Comment: Additional Comments on Occurrence Analysis and Potential Use of a Bayesian Model

EPA has requested comments on the appropriateness of its exposure model to estimate the number of public water systems and populations served by such systems. The American Water Works Association and other water industry associations have suggested that the use of Bayesian modeling is not necessary to support the Agency's regulatory decision-making for perchlorate. Metropolitan suggests that any methodology employed by EPA to interpret occurrence data be consistent with other established methods used with other regulatory development.

Response: EPA continues to evaluate the utility of the Bayesian model(s) in the development of a NPDWR for perchlorate. EPA plans to be transparent in explaining the analysis and any assumptions made when presenting the analysis in connection with the proposed NPDWR. See response to comment code 3150.

Comment: C. Occurrence Analysis 4. Request for Comment on Alternative Approaches a. EPA requests continent on the potential use of a Bayesian model to estimate the number of public water systems, and populations served by such systems, with at least one estimated sample detection greater than 1, 2, 3, 4, 5, 7, 10, 12, 15, 17, 20, and 25 ug/L.

Comment C.4.a.1: Use of a Bayesian model for the stated purpose is not recommended nor supported by the NDEP. The NDEP understands that the national occurrence data for perchlorate were generated between 2001 and 2005. Further, we understand that EPA Method 314 was used for analysis of the occurrence data. The typical reporting limit associated with EPA Method 314 is 4 ug/L. EPA required the collection and submittal of the national occurrence data knowing this limitation.

It is not clear how use of a Bayesian model now for revaluating the existing occurrence data could be considered as a reasonably defensible approach for analysis. This is because it likely will lead to an overestimation of the low- level occurrence of perchlorate if calibrated to select geographical areas and/or small data sets.

Comment: 74 FR 41891: "EPA requests comment on the potential use of a Bayesian model to estimate the number of public water systems and populations served by such systems, with at least one estimated sample detection greater than 1, 2, 3, 4 ug/l, etc."

The Bayesian extrapolation of UCMR1 occurrence data is a complex analysis and therefore EPA needs to be transparent in explaining the analysis in its final regulatory determination. AMWA requests that EPA also clearly state the assumptions of the modeling effort. AMWA recommends that the effort recognize that the data available shows that perchlorate occurrence is not evenly distributed across the country.

Response: EPA continues to evaluate the utility of the Bayesian model(s) in the development of a NPDWR for perchlorate. EPA plans to be transparent in explaining the analysis and any assumptions made when presenting the analysis in connection with the proposed NPDWR. See response to comment code 3150.

Comment: Occurrence Analysis

The Agency requested comments on the appropriateness of using a Bayesian model to estimate perchlorate occurrence in public water systems and populations served by such systems. This estimate would use UCMR1 data that had a laboratory detection level of 4 ug/L and project national occurrence at levels below 4 ug/L. While AWWA recognizes the validity of Bayesian modeling, we believe that the study as proposed is not necessary to support the Agency's regulatory decision making for perchlorate. The weight of evidence as discussed in our comments does not support the need for further analysis of occurrence since regulation of perchlorate would not present a meaningful opportunity for health risk reduction for persons served by public water systems.

Response: The Agency has concluded that there is a meaningful opportunity for health risk reduction for persons served by public water systems through a National Primary Drinking Water Rule for perchlorate. EPA acknowledges that the use of Bayesian modeling is not necessary for making a regulatory determination on perchlorate. EPA continues to evaluate the utility of the Bayesian model(s) in the development of a NPDWR for perchlorate.

Commenter Name: Tom Curtis

EPA Document ID: EPA-HQ-OW-2009-0297-0415
EPA Comment ID: 28854
EPA Comment Code: 3150

Comment: Multiple studies have presented data demonstrating that perchlorate is widely found at low levels and may originate from anthropogenic and/or natural sources; it even occurs in some dietary supplements [FN14: Snyder, S., Pleus, R., Vanderford, B., J. Holady. 2006. Perchlorate and chlorate in dietary supplements and flavor enhancing ingredients. Analytica Chimica Acta, 567:1:26.] and groundwater more than 28,000 years old [FN15: Plummer, L. N.; Bohlke, J. K.; Doughten, M. W. 2006. Perchlorate in pleistocene and holocene groundwater in North-Central New Mexico. Environ. Sci. Technol. 40:1757.]. Since the major route of exposure is food and not water, estimating low level concentrations of perchlorate in the minor source will not provide any additional useful information. The only reason to determine perchlorate concentrations in water is to estimate human exposure. Given the previous discussion and the Agency's assessments, there clearly is sufficient data from human studies that have been completed to sufficiently characterize exposure. These studies (e.g. NHANES, FDA Total Diet Study) examined urine, saliva, and breast milk and in all cases the study subjects had perchlorate. There were no studied individuals who did not have perchlorate. So we know that in the U.S., exposure to perchlorate is very close to universal. Further, examination [FN16: Brandbuber , P, Clark, S. and K. Morley. (publication pending) The Occurrence of Perchlorate in Public Drinking Water Systems, Journal AWWA.] of the existing UMCR dataset provides no general indicator of a causal relationship between occurrence and known locations of perchlorate releases with exception of locations at extremely high levels that were typically adjacent

to industrial and military users of perchlorate. In the vast majority of UCMR occurrences, an obvious source could not be easily identified. Studies [FN17: Jackson, W., Rainwater, K., Anderson, T., Lehman, T., Tock, R., Rajagopalan, S., and M. Ridley. 2004. Distribution And Potential Sources Of Perchlorate In The High Plains Region Of Texas Final Report. Submitted to the Texas Commission on Environmental Quality.],[FN18: Duncan, P.B, Morris, R.D., and E. Vavricka. 2005. Forensic identification of anthropogenic and naturally occurring source of perchlorate. Environmental Forensics, 6:205-215.],[FN19: Dasgupta, P., Martinelango, P., Jackson, W., Anderson, T., Tian, K., and R. Tock. 2005. The Origin of Naturally Occurring Perchlorate: The Role of Atmospheric Processes Environ. Sci. Technol., 39:6:1569 -1575.],[FN20: Balaji Rao, Todd A. Anderson, Greta J. Orris, Ken A. Rainwater,* Srinath Rajagopalan, Renee M. Sandvig, Bridget R. Scanlon, David A. Stonestrom, Michelle A. Walvoord, and W. Andrew Jackson (2007) Widespread Natural Perchlorate in Unsaturated Zones of the Southwest United States Environ. Sci. Technol, 41:4522-4528.] of natural occurrence also do not provide a sound basis for predicting occurrence of perchlorate, unlike other inorganic substances that may associate with specific geological formations such as radionuclides and arsenic.

The Agency has proposed a statistical Bayesian procedure to estimate the distribution of censored perchlorate data. There are several different such procedures (Maximum Likelihood Estimate, Kaplan-Meier Non-Parametric techniques, Regression on Order Statistics) however that all make assumptions about the nature of the distribution, whether normal, log-normal, or non-normal. The Agency has not explained why this particular model would be used versus one of the other approaches noted here. Nor does the Agency explain what population distribution is being assumed. Without this information, it is impossible to comment on the validity of the proposed procedures for this or potentially future applications of this approach. Regardless, all such procedures must assume that a single population of results is being estimated. However there appear to be multiple populations of results, those resulting from natural sources, munitions, Chilean fertilizers, etc. There may, of course, be more than one natural source as cited in the studies previously noted. Given the fact that the occurrence data is mostly poly-modal due to multiple sources in areas such as California and Massachusetts, the use of any statistical procedure that is based on a mono-modal distribution will have little likelihood of producing useful results.

EPA Comment ID: 28891
EPA Comment Code: 3150

Comment: 1. EPA requests comment on the potential use of a Bayesian model to estimate the number of public water systems, and the population served by such systems, with at least one estimated sample detection greater than 1, 2, 3, 4, 5, 7, 10, 12, 15, 17, 20, and 25 ug/L.

With regard to perchlorate's regulatory determination, extrapolating the frequency of occurrence of perchlorate in U.S. drinking water at concentrations less than the MRL of 4 ug/L is unnecessary because scientific data provide no evidence that adverse health effects can occur at these levels. Data for average adults (e.g., Greer et al., 2002) suggest that IUI at water concentrations less than 245 ppb (the drinking water equivalent of the POD) would be statistically insignificant, and the Notice suggests, based on EPA's PBPK model for several life stages, that IUI at water concentrations corresponding to the RfD (i.e., 24.5 ppb) would be less than 2%.

Further, UCMR1 data are insufficient for estimating population sizes exposed to concentrations greater than the MRL of 4 ug/L, and therefore may not be used to reliably estimate exposures below the MRL. As elaborated below, examination of EPA's occurrence analysis is made difficult by the fact that the Notice lacks the required transparency concerning the assumptions it used to calculate sizes of populations potentially exposed to different threshold concentrations (Table 3, U.S. EPA, 2009b). The Notice's summary of the UCMR1 data likely overestimates current exposure concentrations and the number of people exposed to perchlorate above various threshold levels.

Response: See response to comment code 3150. See response to comment code 5220 for an explanation of EPA's rationale in concluding that adverse health effects occur at levels below 24.5 ppb. EPA believes that UCMR1 data are sufficient for estimating population sizes exposed to concentrations greater than the MRL of 4 ug/L. See response to comment ID 28525 under comment code 3140 for an explanation of the EPA's population analysis of UCMR 1 data.

EPA Comment Code: 3150

Comment: 3) Potential use of Bayesian model (page 41891)

ACWA feels that the Bayesian model would not be useful for the purposes of this determination as we already know that at low enough concentrations perchlorate is widely found, if not ubiquitous. Dr. Shane Snyder and others have completed research that indicates perchlorate exists in basically every water source studied and that US exposure to perchlorate is very close to universal. Several human exposure studies (e.g. NHANES) have also looked at urine, saliva, and breast milk and every single study subject in each study had perchlorate--there were no studied individuals who did not have perchlorate. Estimating this data is not necessary when real data is already available.

In addition, since the major route of exposure is food and not water, estimating low level concentrations of perchlorate in the minor source will not provide any additional useful information to determine if this chemical needs to be regulated.

Further, while the USEPA is proposing to use a statistical Bayesian procedure to estimate the distribution of censored perchlorate data, it has not been explained why this particular model would be used and not some other model nor do they explain what population distribution is being assumed. However, all such procedures must assume a single population of results being estimated. In the case of perchlorate, there appear to be multiple populations of results, those resulting from potentially several distinct natural sources, munitions, and Chilean fertilizers. Given the fact that the data should be poly-modal due to these multiple sources found in areas such as California and Massachusetts, the use of any statistical procedure that is based on a mono-modal distribution will have little likelihood of producing useful results.

Again, ACWA appreciates the opportunity to submit comments on this critical determination, and USEPAâ€™s efforts to protect public health through the provisions of the federal Safe Drinking Water Act. We trust USEPA will consider all of the good science that is available when making a final regulatory determination.

If you have any questions, please feel free to call our offices at 916-441-4545 or 202-434- 4760.

Sincerely,

Danielle Blacet Regulatory Advocate

Abby Schneider, Ph.D. Federal Legislative Representative

Response: EPA did not use the Bayesian model to make the regulatory determination on perchlorate. EPA continues to evaluate the utility of the Bayesian model(s) in the development of a NPDWR for perchlorate. EPA may not necessarily distinguish the source of perchlorate in drinking water but does intend to assess the number of water systems impacted by a potential regulation.

EPA Comment Code: 3160 Use of Census data to estimate populations that are in the sensitive life stage

Individual Comments
Commenter Name: James D. Taft

EPA Document ID: EPA-HQ-OW-2009-0297-0525
EPA Comment ID: 28501
EPA Comment Code: 3160

Comment: b. EPA requests comment on using U.S. Census data to estimate the portions of the population that are in the sensitive life stage at any one time.

US Census data are appropriate to estimate the population numbers for subpopulations that may be more vulnerable to perchlorate. As mentioned above, if sensitive subpopulations are going to be considered when making the regulatory determination, accurate estimates of how many people will be protected are critical to the decision.

Response: Please see the response to comment ID 28809 in comment code 3160.

Commenter Name: Jennifer Sass

EPA Comment ID: 28809
EPA Comment Code: 3160

Comment: b. On the use of US Census data to estimate portions of the population that are in the sensitive life stage at any one time

NRDC response: Yes, the U.S. Census data is appropriate for this use.

Yes, EPA should use the U.S. census data. The U.S. census is mandated by the U.S. Constitution, and is conducted every 10 years, with the next one planned for 2010. These data are used by Congress, as well as governments at the local, state, and tribal level to make important decisions about setting priorities, providing services, disbursing funds, and even distributing Congressional seats.[FN62: See e.g. http://2010.census.gov/2010census/] The census data are widely recognized to be reliable, credible, and useful.

There is a valid concern that these data under-represent certain populations, such as certain ethnic minorities, who may be "unregistered" for census purposes. This may be relevant to the use of these data for this perchlorate assessment, because the children of ethnic minorities may not be fully represented. If anything, these data would underestimate the number of children under 1 year old.

Response: Please see response to comment ID 28867 under comment code 3160. EPA will further take into consideration the effect contaminants have on subgroups that comprise a meaningful portion of the general population (such as infants, children, pregnant women, the elderly, and

individuals with a history of serious illness) as we develop the proposed NPDWR, as required by Section 1412(b)(1) of the Safe Drinking Water Act.

EPA Comment ID: 28867
EPA Comment Code: 3160

Comment: 4(b)) EPA requested comments on using US Census data to estimate the portions of the population that are sensitive at any one time to perchlorate in drinking water. This analysis is used as one factor in EPA's decision-making on the need for a drinking water standard for perchlorate, based on the number of people in the U.S. who would be at risk. MassDEP believes that it is inappropriate to consider sensitive groups one-by-one using census or any other data. EPA should certainly consider perchlorate exposures to fetuses, infants and young children up to 2 years of age. However, EPA should also, for several reasons, consider the entire population's exposure. First, Blount et al. (2006) and Steinmaus et al. (2007) reported an association between perchlorate exposure and decreased T4 and increased TSH in iodine deficient adult women and increased TSH in all women. As such, we believe that all women should be included in EPA's analysis as a sensitive subgroup. Secondly, as previously noted, there are other sensitive members of the population beyond fetuses, infants and women, and they should also be factored into EPA's framework for considering the extent of the population at risk to perchlorate exposures from drinking water. Lastly, because significant exposures to other thyroid toxicants are known to occur, other members of the population may also be at increased risk. Thus, any estimate derived based on exposures to the fetus, neonate and women as a group will still be an underestimate of those actually at risk.

We appreciate the opportunity to comment. For further information please contact Carol Rowan West at 617-292-5510 (Carol.RowanWest@state.ma.us), C. Mark Smith at 617-292-5509 (C.Mark.Smith@state.ma.us) or Tsedash Zewdie at (617) 292-5842 (Tsedash.Zewdie@state.ma.us).

Response: EPA considered the population estimates served by PWSs that were monitored under UCMR 1 for which the highest reported perchlorate concentration was greater than various threshold concentrations when determining that a regulation for perchlorate was warranted. These population estimates are for people at all life stages. EPA has determined that a NPDWR for perchlorate could reduce perchlorate exposures for these populations to levels below the potential alternative HRLs that EPA has identified as levels of public health concerns for purposes of this determination, and that such exposure reductions present a meaningful opportunity for the reduction of health risks for persons served by PWSs. Please see the final regulatory determination notice for further discussion of this analysis.

EPA Comment ID: 28893
EPA Comment Code: 3160

Comment: 2. EPA requests comment on using U.S. Census data to estimate the portions of the population that are in the sensitive life stage at any one time.

U.S. Census data might be useful if PWS data are paired with U.S. Census data for the same locations. As discussed above, the relevance of the UCMR1 data to current exposure is unclear since the UCMR1 data, which were collected from 2001 to 2005, likely overestimate current concentrations, and approximately half of the perchlorate water samples in the UCMR1 database are from untreated source waters. Evaluating perchlorate in drinking water at low concentrations (e.g., less than the concentration corresponding to the RfD of 24.5 ppb) is unnecessary as no adverse health effects are expected at these levels.

Response:
Please see response to comment ID 28809 under comment code 3160.

EPA acknowledges that there may be sources that had detected perchlorate from UCMR1 monitoring that are either no longer being used or are being treated per the requirements of maximum contaminant levels established in California and Massachusetts; however, the 1996 amendments to the Safe Drinking Water Act require the Agency to consider the best available, peer reviewed science when developing drinking water standards. In applying these principles, "best available" usually refers to the availability at the time an assessment is made. UCMR data is the most

extensive nationally representative occurrence data for perchlorate in public water systems; therefore, EPA analyzed this data and additional occurrence data in making a regulatory determination for perchlorate as required by SDWA Section 1445.

EPA disagrees with the commenter that approximately half of perchlorate water samples in the UCMR 1 database are from untreated source waters. The data EPA used to evaluate perchlorate occurrence from UCMR1 was only taken from finished water. EPA did allow monitoring at source water sampling points; however, if perchlorate was detected in a source water sample, the UCMR 1 required that follow-up samples be collected at the entry point to the distribution system and follow the monitoring frequency specified in the rule for the contaminant and water source type.

EPA disagrees that evaluating perchlorate in drinking water at low concentrations (e.g., less than the concentration of 24.5 ppb) is unnecessary. Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination. For further discussion of this issue please see today's notice.

EPA Comment Code: 3170 Accounting for variation of perchlorate levels in public water systems over time

Response to Code 3170: EPA has decided to regulate perchlorate in drinking water. See response to comment code 6120. EPA notes that systems or entry/sample points with at least one detect above the threshold may not expose the population to this level at all times. At any particular time, perchlorate levels may be lower or higher than the highest estimated sample detection. However, EPA believes that estimating the number of systems, entry points and populations with at least one detection above the various threshold concentrations identified in the final perchlorate regulatory determination notice is appropriate for the perchlorate regulatory determination because a single quarterly or semi-annual sample more closely reflects the short term exposure during the life stages identified by the NRC (i.e., fetuses, pre-term newborns, infants and young children) than does the estimated mean concentration of perchlorate at a system.

EPA Document ID: EPA-HQ-OW-2009-0297-0525
EPA Comment ID: 28502
EPA Comment Code: 3170

Comment: c. EPA requests comment on how the Agency should account for the variation of perchlorate levels over time in public water systems. EPA believes that estimating the number of systems, entry points and populations with at least one detection above the HRL is appropriate for the perchlorate regulatory determination because a single quarterly or semi- annual sample more closely reflects the short term exposure during life stages of concern (i.e., fetuses, pre-term newborns, infants and young children). However, EPA requests comment on whether the Agency should consider other approaches such as estimating the number of systems, entry points and populations with two or more detections above HRL or some other approach.

ASDWA agrees with EPA's premise that a single occurrence above the HRL could indicate a cause for concern about health impacts due to short term exposure, if the value is not an anomaly. However, on the other hand, a single value above the HRL, especially if the HRL is 15 ug/l or almost 4 times the MRL, that is not supported by additional detections in other samples, could be questionable and indicative of a sampling or laboratory error. EPA should consider an analysis that considers a single sample above the HRL, but with additional detects, as the occurrence criteria. This considers the impact of short term possible health impacts but would tend to eliminate outliers.

Response: See response to comment code 3170. EPA intends to present the perchlorate occurrence analysis that is used to develop the NPWDR.

EPA Comment Code: 3170

Comment: c. On how the Agency should account for the variation of perchlorate levels over time, based on estimating the number of systems, entry points and sampling.

NRDC Response: If EPA plans to consider the low-end estimate of the population exposed, it must develop a justifiable estimate.

As part of the occurrence analysis, EPA attempted a high-end and a low-end estimate of the population exposed to perchlorate from contaminated drinking water. The high-end estimate, which is the population served by a system with a contaminated entry-point is an appropriate point to use. However, EPA did not employ the best method to estimate population exposure for the low-end estimate. For systems with multiple entry points, EPA estimated an equal proportion of the population was served by each entry point. However, EPA acknowledged that "[t] his approach may provide either an overestimate or an underestimate of the population served by the affected entry point" but failed to provide any reasonable uncertainty analysis. An uncertainty analysis is a mathematical measure of the "goodness" of the result, and therefore our confidence in it. With such an analysis it is impossible to determine the fitness of the value as a basis for making regulatory decisions related to health protection or scientific quality. Therefore, EPA cannot justify using this estimate to model the occurrence of and exposure to perchlorate in drinking water.

There are two problems with assuming that every entry point equally serves a population. First, it is possible that one entry point could serve a large majority of the population and other entry points serve many fewer. Basing the estimate on the proportion of the flow rate of water sent to the system by a given entry point would provide a more accurate representation of the population exposed. Second, having a detection at one entry point does not preclude the possibility that other entry points in the system are also contaminated. For example, one groundwater source may distribute

water to multiple wells which separately contribute water to a system. Therefore, assuming that one contaminated entry point contributes equally to the flow of the entire distribution system is a weak way to estimate the population exposed. Because EPA can neither determine whether this estimation is an overestimate or an underestimate, or provide an analysis of the uncertainty, it should not be used as part of the regulatory determination for perchlorate.

NRDC Response: Estimating the water systems with at least one entry point with a sample above the detection limit is appropriate for the perchlorate regulatory determination.

The perchlorate monitoring program was not designed to specifically detect high levels of perchlorate. While we are not aware of evidence that there are large fluctuations of perchlorate levels in groundwater, detecting perchlorate in drinking water is a signal of a bigger, not smaller, contamination problem. When sporadic sampling is conducted in a system - such as taking a single quarterly or semi-annual sample - detections of contamination are a reflection of a widespread problem. It much more likely that a monitoring program would miss detections and particularly elevated spikes, rather than catch them. Much like searching for a needle in a haystack,if you find one, it is likely because there are many more; however if you don't find one, that does not mean there are none. Therefore, each finding of contamination in monitoring data should be treated seriously, as if it is representative of a widespread problem.

Response: For a discussion on variation of perchlorate levels over time see response to comment code 3170. For a discussion of the analysis EPA used to derive the population estimates that EPA considered in the final regulatory determination see response to comment ID 28525 under comment code 3140. EPA believes that an uncertainty analysis is unnecessary due to the fact that the Agency not only considered central value estimates, as the commenter requested, but the Agency evaluated high end estimates as well. Please see response to comment ID 20952 under comment code 3140.which explains in detail what EPA did to account for high and low end population estimates. EPA agrees that each finding of contamination should be taken seriously and that is part of the reason that we have determined that perchlorate occurs or there is a substantial likelihood that perchlorate will occur with a frequency and at levels of public health concern in public water systems.

EPA Comment ID: 28894
EPA Comment Code: 3170

Comment: 3. EPA requests comment on how the Agency should account for the variation of perchlorate levels over time in public water systems. EPA believes that estimating the number of systems, entry points and populations with at least one detection above the HRL is appropriate for the perchlorate regulatory determination because a single quarterly or semiannual sample more closely reflects the short term exposure during life stages of concern (i.e., fetuses, preterm newborns, infants and young children). However, EPA requests comment on whether the Agency should consider other approaches such as estimating the number of systems, entry points and populations with two or more detections above HRL or some other approach.

As discussed above, there are fundamental scientific and statistical issues with the UCMR1 database for estimating current exposures to perchlorate in drinking water, so any application of the data therein would be unreliable. First, UCMR1 data are likely to overestimate current exposure concentrations because data were collected from 2001-2005 and subsequent remediation and treatment has reduced these concentrations, and approximately half of the perchlorate water samples in the UCMR1 database are from untreated source waters. Second, data in the UCMR1 database are insufficient for estimating population sizes because, for PWSs with multiple entry points to the distribution system, the database does not specify the size of subpopulations distributed water from specific entry points where perchlorate was detected.

Response: EPA acknowledges that there may be sources that had detected perchlorate from UCMR1 monitoring that are either no longer being used or are being treated per the requirements of maximum contaminant levels established in California and Massachusetts; however, the 1996 amendments to the Safe Drinking Water Act require the Agency to consider the best available, peer reviewed science when developing drinking water standards. In applying these principles, "best available" usually refers to the availability at the time an assessment is made. UCMR data is the most extensive nationally representative occurrence data for perchlorate in public water systems; therefore, EPA analyzed this data and additional occurrence data in making a regulatory determination for perchlorate as required by SDWA Section 1445.

EPA disagrees that data in the UCMR1 database are insufficient for estimating population sizes. EPA presents in today's Federal Register notice a range of estimates of the population served by PWSs that had at least one sample with perchlorate concentrations greater than the threshold concentrations. The population range represents both a high end estimate, as well as a central value estimate, both derived using the UCMR 1 monitoring data. The high end estimate of the population served drinking water above a threshold is derived by adding the entire system population of all PWSs in which at least one sample was found to contain perchlorate above the threshold. Many PWSs have multiple entry points into which treated water is pumped for distribution to their consumers. For the PWSs with multiple entry points, it is unlikely that the entire service population receives water from the one entry point with the highest single concentration. Therefore, EPA also provides a central value estimate of the population served water with perchlorate above a threshold in today's notice. EPA developed this central value estimate by assuming the population was equally distributed among all entry points and added only the proportion of the total population served by those entry points in a PWS that had at least one sample with perchlorate concentrations greater than the threshold.
In regards to the commenter's concern that approximately half of the perchlorate water samples in the UCMR1 database are from untreated source waters, please see response to comment ID 28893 under comment code 3160.

EPA Document ID: EPA-HQ-OW-2009-0297-0527
EPA Comment ID: 28915
EPA Comment Code: 3170

Comment: As discussed in the notice, short-term exposures during sensitive life stages are of concern for perchlorate. We agree that the short time frame of concern should be considered in evaluating perchlorate's occurrence. The NJDEP (2009) MCL proposal considers the short

timeframe of concern for perchlorate in its notification and monitoring requirements. If a public water system receives results of a sample which exceed the MCL, a confirmation sample must be taken within 72 hours, as opposed to within two weeks for contaminants with chronic health effects. Enforcement of the MCL will be based on the average of the initial sample and the confirmation sample. Also, public notification of an MCL violation must take place with 14 days, as opposed to 30 days for contaminants ith chronic health effects.

Because of the short time period of exposure that is of concern for perchlorate, we agree with USEPA that data for systems, entry points, and populations with at least one detection above the HRL should be used in the regulatory determination. We agree that it is appropriate to base the occurrence analysis for the regulatory determination on the maximum concentration detected rather than on the average concentration.

Response: See response to comment code 3170. EPA agrees with the commenter in regards to basing the occurrence analysis on the maximum concentration detected.

EPA Document ID: EPA-HQ-OW-2008-0692-0681
EPA Comment ID: 20021
EPA Comment Code: 3200

Comment: Perchlorate is a contaminant found in drinking water in California and at least 34 other states. It interrupts the uptake of iodine in the thyroid and may adversely affect thyroid function, which can then interrupt many hormones in the body. Infants, children, and pregnant women are particularly vulnerable populations.

As of 2005, there were 456 drinking water sources with perchlorate detections in 12 counties in California. In our county, an 18 square mile plume of perchlorate contamination requires the monitoring and remediation of hundreds of water wells. Although the source of Santa Clara County's perchlorate contamination and discharger has been identified, drinking water quality is not expected to return to baseline levels for at least 12 years at best.

Response: Using the criteria mandated by the 1996 SDWA Amendments, EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. See response to comment code 6120.

Commenter Name: Diane VanDe Hei
Commenter Organization: Association of Metropolitan Water Agencies (AMWA)
EPA Document ID: EPA-HQ-OW-2009-0297-0494
EPA Comment ID: 28829
EPA Comment Code: 3200

Comment: Population Estimates

AMWA agrees with EPA that its population estimate is high for systems with at least one perchlorate detection and multiple entry points into the distribution system. This is because EPA based the estimate upon the assumption that an entire system's population would be served water from the entry point with the perchlorate detection. However, in systems with multiple entry points, AMWA agrees it is unlikely that the system's entire service population would receive water that contains perchlorate at the highest concentration detected at a single entry point.

In addition, AMWA agrees with comments referenced by EPA on page 41890 of the FR notice that some states have higher concentrations of perchlorate in drinking water than others. In addition, the exposure to perchlorate of the population in states that already have regulatory limits for perchlorate will be capped at those levels. For example, staff from the Massachusetts Department of Environmental Protection indicated to AMWA that it will possibly require the PWS with the highest concentration of perchlorate during the commonwealth's last compliance sampling round to shut

down its well and find a new source of water for its service population. Compliance data for the Los Angeles Department of Water and Power (Appendix A [see PDF docket ID EPA-HQ-OW-2009-0494]) shows very few detections, with all samples below California's MCL of 6 ppb.

With regard to UCMR data, many of the utilities in the southwest and western states with perchlorate detections have since seen their concentrations drop. Whether because of state standards, local cleanups at the Tronox (formerly Kerr McGee) facility or for other reasons, EPA must take this into consideration in its final population estimates. For example, SNWA had perchlorate detections in 2003 ranging from 10 - 17 ppb. Today the concentrations range from 1 to 3 ppb. There are many utilities in CA and AZ that are served by Metropolitan Water District (MWD) of Southern California and the Central Arizona Project that had detections in the range of 3 to 6 ppb in 2002 to 2004 that have not had detections of perchlorate in the last 2 years. For example, please see the data from Consumer Confidence Reports from Phoenix (http://phoenix.gov/ftpalias/payf/qualre05.pdf) and Scottsdale (http://www.scottsdaleaz.gov/AssetFactory.aspx?did=28404). In addition, AMWA is also providing annual average perchlorate concentrations from the Alfred Merritt Smith Water Treatment Facility (AMSWTF) at the Southern Nevada Water Authority (Appendix B [see PDF docket ID EPA-HQ-OW-2009-0297-0494]), and MWD data from the Whittsett intake (Appendix C [see PDF docket ID EPA-HQ-OW-2009-0297-0494]). This is raw water data from the Colorado River intakes at these utilities, which is blended with local water supplies.

EPA also should take care to recognize in its population exposure estimates the differences between perchlorate in ground water and surface water. Many groundwater systems do not run all of the system's wells continuously. Wells with higher concentrations of perchlorate may be blended with lower concentrations, causing a diluting effect. Concentration of surface water sources may change due to precipitation. These factors could cause EPA's estimates to be more conservative than stated in the NODA.

It is important for EPA to properly characterize its estimates of the potential population exposed to perchlorate. AMWA recognizes that these estimates include ranges, but the best data available must be used so that these estimates are as thoughtful and accurate as possible. Overestimating the populations affected would effectively lead to an overestimation of the benefits. Overestimating populations affected by perchlorate exposure in drinking water could also effectively build a basis for a body of literature that mischaracterizes the situation, which could then be perpetuated and misused as the information is referenced in the future.

Response: EPA acknowledges that there may be sources that had detected perchlorate from UCMR1 monitoring that are either no longer being used or are being treated per the requirements of maximum contaminant levels established in California and Massachusetts; however, the 1996 amendments to the Safe Drinking Water Act require the Agency to consider the best available, peer reviewed science when developing drinking water standards. In applying these principles, "best available" usually refers to the availability at the time an assessment is made. UCMR data is the most extensive nationally representative occurrence data for perchlorate in public water systems; therefore, EPA analyzed this data and additional occurrence data in making a regulatory determination for perchlorate.
EPA agrees that it is important to properly characterize the estimates of potential population exposed to perchlorate. Please see response to comment ID 28810 in comment code 3170.

Commenter Name: Diane VanDe Hei
Commenter Organization: Association of Metropolitan Water Agencies (AMWA)
EPA Document ID: EPA-HQ-OW-2009-0297-0494
EPA Comment ID: 28838
EPA Comment Code: 3200

Comment: With regard to using data from the Commonwealth of Massachusetts to help characterize the distribution of very low perchlorate concentration occurrence, AMWA is concerned about extrapolating these data to determine a nationwide distribution for two reasons. First, 89% of public water systems in Massachusetts are solely groundwater systems. In addition, a large number of these systems are non-community water systems. Secondly, the mechanics of perchlorate persistence and occurrence in ground water across the country differ due to factors such as soil retention, subsurface geology, etc.

Therefore, AMWA recommends that EPA extrapolate this data nationwide only for systems that use groundwater, taking care to recognize the proportion of Massachusetts data that are community water systems vs. non-community water systems as well as the differences in other factors that would likely affect these numbers.

Response: EPA did not extrapolate data from Massachusetts nationwide to aid in the determination of a regulation for perchlorate. EPA did analyze the best available and most extensive nationally representative occurrence data from UCMR along with additional occurrence data, and concluded that regulation of perchlorate was warranted. The Agency evaluated supplemental drinking water monitoring data for perchlorate from California and Massachusetts, and believes that these States' monitoring results are generally consistent with the results EPA collected under the UCMR 1.

EPA Comment Code: 3300 Other drinking water occurrence studies, models, and data for EPA to consider (besides UCMR 1 and California and Massachusetts data already evaluated)

Response to Code 3300: Thank you for providing additional data on the occurrence of perchlorate. In August 2009, the Agency sought comments on additional approaches to analyzing data related to EPA's perchlorate regulatory determination. These additional comments were sought in an effort to ensure consideration of all the potential options for evaluating whether there is a meaningful opportunity for health risk reduction of perchlorate through a national primary drinking water rule. EPA evaluated the additional occurrence data received and has considered it along with the UCMR 1 data, which is currently the best available and most extensive nationally representative monitoring program for perchlorate in public water systems.

Using the criteria mandated by the 1996 SDWA Amendments, EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. See response to comment code 6120.

EPA Comment Code: 3300

Comment: The Suffolk County Department of Health Services (SCDHS), located within the County of Suffolk, in New York State, has conducted a search of our records for the past 10 years as it relates to sampling for the chemical perchlorate. The Department has found that of the 5882 samples obtained for perchlorate analyses, between 1998 and 2008, approximately 420 samples were found to contain perchlorate with concentrations that ranged between 1ppb and 49 ppb - with the mean value of 7.17 ppb. This data indicates that approximately 7% of these samples that were checked for perchlorate contained the chemical. It should be noted that of the 420 samples that were positive, 18 were found in community water supply distribution systems; 49 were found in non-community public water supply wells, and 351 were obtained from private wells.

The Long Island aquifer has been designated as "sole source" by the USEPA and is particularly sensitive to perchlorate discharges, due in part to the sand and gravel material that exist above and within our aquifer systems. The Department has been involved with determining and remediating the sources of perchlorate plumes impacting public and private wells within our County. An extensive amount of time, effort and cost was expended by the Department in performing these tasks.

Comment: A Uniform Federal Drinking Water Standard is Necessary to Protect Public Health

On the merits of EPA's preliminary determination, based on an initial review, the Department submits that perchlorate is present in ground and surface drinking water at levels of public concern and that establishment of a drinking water standard presents a meaningful opportunity to reduce the health risk perchlorate presents, particularly to the vulnerable and sensitive subpopulations - pregnant and lactating women, fetuses, and young children. There are no technological impediments to removing perchlorate from ground or surface water. Technology capable of removing perchlorate from ground and surface water is already in use. For larger surface water systems eliminating or reducing the source of the contamination would likely be the most practical solution.

Section 1412(b)(1)(A) of the Safe Drinking Water Act requires EPA to establish a maximum contaminant level for a contaminant if: (1) the contaminant may have an adverse effect on the health of persons; (2) the contaminant occurs or presents a substantial likelihood that it will occur in public water systems at a frequency and at levels of public concern; and (3) EPA determines that regulation of the contaminant presents a meaningful opportunity for health risk reduction for persons served by public drinking water supplies. In the case of perchlorate, each of the criteria is satisfied.

There is no genuine dispute that perchlorate may have an adverse effect on human health. Perchlorate is known to interfere with thyroid function. Lower thyroid hormone levels can cause changes that adversely impact brain development. In its preliminary determination, EPA acknowledges that at sufficiently high doses, perchlorate can interfere with thyroid function in pregnant women, fetuses, newborns and young children.

In Maryland, perchlorate is present at significant levels in ground and surface water at three Department of Defense facilities. At Aberdeen Proving Ground in Harford County, Maryland, perchlorate has been detected in groundwater at seven different locations and at levels as high as 350 parts per billion ("ppb"). Perchlorate from other areas of the installation has contaminated the water supply for the City of Aberdeen. In the absence of a federal drinking water standard, the State has set an advisory level of 1 ppb for the City treatment system's finished water.

Although no public drinking water supply wells have been impacted, perchlorate levels in ground water at the Naval Support Facility at Indian Head have been detected at levels as high as 2,900 ppb. At a number of other sites in Cecil County, Maryland, perchlorate contamination was detected in ground water monitoring wells at levels as high as 230,000 ppb in the late 1990's. In the one case where perchlorate contamination has impacted the drinking water supply, the Department has provided bottled water to affected residents and required installation of a treatment system to address the contamination. Perchlorate contamination has also been detected in the Potomac River, the source of drinking water for millions of Maryland, Virginia, West Virginia and District of Columbia residents. EPA sampling detected perchlorate levels up to 8 ppb in one of Maryland's Potomac River water supply intakes.

Establishing a federal drinking water standard that would protect the millions of people, including pregnant women, infants and young children, who are served by drinking water that is currently contaminated or at risk of contamination by perchlorate is necessary to protect public health.

Response: EPA agrees with the commenter that the three criteria for determining whether a contaminant should be regulated from SDWA section 1412(b)(1) are satisfied for perchlorate. Please see the responses to comment codes 6120 and 3300.

Comment: Occurrence

As noted above, one of the criteria for evaluating the need for potential regulatory actionis occurrence. In 2005, AWWA prepared an assessment of data collected under the first Unregulated Contaminant Monitoring Rule (UCMR1). AWWA recently completed a follow-up of this initial assessment using the final UCMR1 data set considered by EPA in this proposed decision. There were very subtle differences, in total numbers, but that did not result in a significant difference in the overall findings. This analysis is summarized below and has been submitted to a peer-reviewed journal and is pending publication.

The evaluation by Brandhuber et.al. (pending publication) consolidated existing potable water perchlorate occurrence information taken from UCMR1 and other recently completed occurrence studies. The detection of perchlorate in drinking water was determined to be geographically widespread but at very low concentrations. Significantly, there was little correlation between perchlorate detection in drinking water and known points of perchlorate release to the environment identified by the USEPA. Perchlorate has been detected in drinking water in at least 26 States and Puerto Rico and in approximately 5% of the nation's large community water systems (>10,000 population served). When detected, perchlorate was typically present at concentrations of less than 12 ug/L and was generally found in less than one half of the sources for systems which sampled multiple sources. No statistically significant difference in the rate of perchlorate occurrence between surface and ground waters was identified.

Extrapolating the results of the occurrence studies reviewed by this report, it appears that nationally less than 1% of all drinking water systems would be impacted if an MCL of 20ug/L were established. An MCL of 2 ug/L could impact approximately 4% of public water systems nationally. At this level, regional impacts in California and Texas would be greater due to the higher geographical concentration of detections in those states. Yet it should be noted that water systems in Massachusetts, New Jersey and California have already established regulatory limits of 2 ug/L, 5 ug/L and 6 ug/L respectively, thereby capping the population exposure potential from community drinking water sources in those states.

The estimated population exposure calculated from UCMR1 findings has also been greatly reduced by the effectiveness of mitigating contamination sources on the Colorado River to levels below 2 ug/L. This reduction in levels in the Colorado River alone represents a reduction in the exposure potential of approximately 20 million persons in several western states, primarily California and Arizona. In addition, a recent telephone survey of water systems detecting perchlorate indicated that at least 50 MGD of water production has been taken off line nationally due to the presence of perchlorate since UCMR1 monitoring was completed.

Response: Thank you for providing the additional analysis of data on the occurrence of perchlorate. EPA notes that New Jersey proposed an MCL of 5 µg/L in April 2009, but this standard has not been finalized. In July 2006, Massachusetts set an Maximum Contaminant Level (MCL) of 2 µg/L. Additionally, In October 2007, California set an MCL of 6 µg/L. Please see response to comment ID 28755 in comment code 3300. Using the criteria mandated by the 1996 SDWA Amendments, EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. See response to comment code 6120.

Water Docket Environmental Protection Agency Mailcode 2822 T 1200 Pennsylvania Ave., NW Washington, DC 20460

Re: Docket ID No. EPA-HQ-OW-2008-0692 Drinking Water: Preliminary Regulatory Determination on Perchlorate, FR 10/10/08

Gentlemen:

On behalf of the Long Island Water Conference, an association of public water supply professionals in Nassau and Suffolk Counties in NY, I am pleased to present our comments on the referenced preliminary regulatory determination.

Our member suppliers have a long history of responsiveness in meeting the increasing needs for comprehensive water supply monitoring, research and groundwater protection programs. We have

worked cooperatively with our regional regulatory agencies to provide monitoring and oversight that dramatically exceeds federal EPA requirements. Aggressive monitoring is necessary and desirable in protecting public health. We have also worked with regional regulatory agencies in water supply and water resource management studies and supported the integration of local regulations which combine discharge controls, land use, and the storage of hazardous substances into an advanced source water protection system.

Long Island was one of the first designated Sole Source Aquifer systems in the United States, and with a total population of nearly three million, is considered to be one of the most intensively used and critical Aquifer systems in the country.

This preliminary regulatory determination therefore is significant to every public water supplier on Long Island. Approximately 250 community water supply wells in Nassau and Suffolk County have indicated detection of perchlorate in concentrations greater than 1 ppb. Consistent with EPA's occurrence evaluation, a much smaller number of sources exhibit concentrations greater than 5 ppb (approximately 25) or 10 ppb (approximately 10). The Health Reference Level (HRL) of 15 ppb used by EPA to reach this determination is close to the NYS Department of Health's Action Level (discussed below); no Long Island public water supplier customer is being currently exposed to concentrations in excess of this Level.

Response: Please see the response to comment code 3300.

EPA Comment Code: 3300

Comment: We do not have a technical basis upon which to criticize EPA's determination. Based upon its interpretation of Safe Drinking Water Act criteria, EPA has determined there is not a "meaningful opportunity for health risk reduction" through a national drinking water regulation. EPA's conclusion is based upon its own analysis of available data indicating that perchlorate was found at levels of public health concern (the HRL) in less than 1 percent of public drinking water systems sampled.

However we do wish to point out that without a greater understanding of perchlorate formation processes and the possibility that unmeasured perchlorate may exist in other salts in common use, one may still lack statistical confidence in utilization of the UCMR data to estimate population exposures in drinking water. Unlike other parts of the country, a clear source for many of Long Island's perchlorate contamination occurrences has not emerged over the past 10 years. The highest recorded perchlorate concentration in a well on Long Island was traced to a completely unregulated activity, as described below.

Perchlorate monitoring of public water supplies on Long Island began in the spring of 1998. Initially in response to perchlorate detection reports elsewhere in the US, the Suffolk County Water Authority (SCWA) voluntarily collected samples from wells at five wellfields. The samples were sent to the Montgomery Watson Laboratory for analysis. Of the initial sample results one well - #3 at the Old Country Road wellfield in Westhampton - indicated a concentration of perchlorate of 30 ppb.

The SCWA removed this well from service. At the end of 1998, NY State Department of Health provided an Action Level of 18 ppb. This well later showed concentrations as high as 127 ppb in samples collected during subsequent test pumping. Initial thoughts were directed to the former military uses of property immediately upgradient of the well at a former BOMARC missile site. This was discounted, upon submission of evidence that solid fuel rockets were not deployed at this site.

By late 1998, attention turned to a review of more recent activities subsequent to the takeover of the BOMARC site by Suffolk County - specifically the Suffolk County Police Department (SCPD) practice of disposal of confiscated fireworks and munitions by burning. Between November 1998 and February 2000, a total of 18 profile wells were installed by the Suffolk County Department of Health Services' (SCDHS) Bureau of Groundwater Resources in locations upgradient and downgradient of the fireworks disposal pit, which was located in the northwest corner of the site. Groundwater flow direction and water quality data appeared to eliminate other activities in the area as potential sources. Perchlorate was detected in 9 test wells downgradient of the pit, in concentrations as high as 3,370 ppb. Although the pit and burning practices have been modified, fireworks disposal at the site continues, and to date such disposal is not covered under any NY State environmental regulation. In subsequent years, SCDHS also investigated the contamination of a number of private wells and one non- communitysupply well in Yaphank, NY, which later traced to fireworks testing and a practice of stabilizing "dud" fireworks by a process called "soaking." This process utilizes water indrums to leach out the perchlorate from the dud, stabilizing the firework for subsequent disposal by burning.

Local laboratory capacity has been developed at SCWA, SCDHS and at private labs to assist in the monitoring effort, which began in earnest before the UCMR implementation date, and monitoring continues.

Response: Please see response to comment code 3300.

Comment: November 6, 2008

Attention: Docket ID Number EPA-HQ-OW-2008-0692 OSWER Docket EPA Docket Center Mailcode: 2822T Environmental Protection Agency 1200 Pennsylvania Ave., NW Washington, DC 20460

Dear Environmental Protection Agency:

The Metropolitan Water District of Southern California (Metropolitan) is submitting comments on U.S. Environmental Protection Agency's (EPA's) Preliminary Regulatory Determination on Perchlorate (73 Federal Register 60262). The proposed action by the EPA not to regulate the drinking water contaminant perchlorate will affect how state and local officials can respond to localized perchlorate contamination.

Metropolitan is a regional water supply agency that provides supplemental water to nearly 19 million people throughout the southern California area. Our major source of supply, the Colorado River, was contaminated from industrial production of perchlorate for solid rocket fuel and subsequent improper disposal methods. Perchlorate contaminated groundwater seeping into Lake Mead through the Las Vegas Wash area found its way into the Colorado River, which supplies Metropolitan and other downstream users. Levels as high as 20 parts per billion (ppb) were detected in Lake Mead and levels as high as 9 ppb have been detected at the intake to Metropolitan's conveyance system. Following the detection of perchlorate in the Colorado River, Metropolitan along with the EPA and regulatory agencies in Nevada, organized the forces necessary to successfully treat and decrease the sources of perchlorate loading. Since 2006, monitoring has indicated levels at or below 2 ppb entering Metropolitan's conveyance system.

Comment Clerk Water Docket Environmental Protection Agency Mail Code: 2822T 1200 Pennsylvania Ave., NW. Washington, DC 20460

Re: Arizona Department of Environmental Quality Comments on Federal Preliminary Regulatory Determination on Perchlorate Docket EPA-HQ-OW-2008-0692

Dear Sir:

In response to the notice in the Federal Register of October 10, 2008 (Volume 73, Number 198) the Arizona Department of Environmental Quality (ADEQ) is offering comments on the Preliminary Regulatory Determination on Perchlorate. ADEQ offers these comments in role of the delegated authority responsible for protecting public health in Arizona through rules promulgated under the Federal Safe Drinking Water Act.

Perchlorate contamination is known to be present in Arizona water supplies. Arizona, along with other arid western states, relies heavily upon the Colorado River as a critical source of our population's drinking water supply. The overall "health" and water quality of the Colorado River and other surface water sources are of the utmost concern for Arizona. Perchlorate contamination has impacted the Colorado River due to industrial sources in the Las Vegas area. The source of this contamination has been controlled more effectively by the responsible parties; however the risk of perchlorate contamination in the Colorado River water supply still exists.

A Consumer Confidence Report issued by the City of Phoenix (City) in 2007 is one example of a direct perchlorate related impact on Arizona citizens. According to City records, roughly ninetyeight percent of all potable water produce annually is derived from surface sources, including water from the Colorado River. In 2004, the City collected 392 finished water distribution samples (as a

precautionary measure) to gather more information on the occurrence of perchlorate in the public water system supply. Thirty-nine of those samples tested at, or above, the minimum detection level of four (4) part per billion for the presence of perchlorate.

Perchlorate contamination is not strictly limited to surface waters of the Southwest. A perchlorate occurrence study conducted by ADEQ (Perchlorate in Arizona: Occurrence Study of 2004) revealed numerous groundwater sources with detectable levels of perchlorate. One well located in Yuma County tested positive in 2004 for levels of perchlorate in the 15 parts per billion (ppb) range. Groundwater is a critical source of drinking water in Arizona and under Arizona law all aquifers in the state are designated by statute for drinking water use.

EPA Comment ID: 20933
EPA Comment Code: 3300

Comment: Nevertheless, the limited available drinking water data that the Environment Department has reviewed show significant perchlorate contamination in several public drinking water systems around the State. In the Department's view, perchlorate contamination in drinking water occurs at levels and at a frequency that is a public health concern in New Mexico.[FN2: See SDWA [section] 1412(b) (1)(A)(ii), 42 U.S.C. [section] 300g-1(b)(1)(A)(ii) (Westlaw 2008).]

At Cannon Air Force Base, near Clovis, New Mexico, the Environment Department received data in 1999 showing perchlorate concentrations of 46 micrograms per liter (ug/L) in production well PW-2 and 21 ug/L in production well PW-7. These wells are both active drinking water production wells that serve users on the Base.[FN3: N.M. Environment. Dep't, Perchlorate Survey 2001 Final Report, vol. 1, tab "Cannon" (unpublished compilation).] Data that the Environment Department gathered in 2001 from Cannon showed perchlorate contamination of 23.5 ug/L in PW-12, another drinking water production well.[FN4: Id.] Data collected from the system in 2003 and submitted to the Environment Department under the Unregulated Contaminant Monitoring Ruleshows a perchlorate level at 30 ug/L.[FN5: Safe Drinking Water Information System, State version (SDWIS/State). The State has not verified the accuracy of this data.] In addition, the Government Accountability Office (GAO) has compiled data on perchlorate contamination throughout the United States, including New Mexico. In its 2005 report, GAO similarly reported perchlorate at 46 ug/L in drinking water at Cannon Air Force Base.[FN6: GOVERNMENT ACCOUNTABILITY OFFICE, A SYSTEM TO TRACK SAMPLING AND CLEANUP RESULTS IS NEEDED, AT 37 (GAO-05-462) (May 2005).]

At the Melrose Bombing Range, also near Clovis, the Environment Department received data in 1999 showing perchlorate contamination in production well PW-11, an active drinking water production well for the facility, at 25 ug/L.[FN7: N.M. Environment. Dep't, Perchlorate Survey 2001 Final Report, vol. 2, tab "Melrose" (unpublished compilation).] Data the Environment Department obtained in 2001 from Melrose showed perchlorate concentrations of 30.3 ug/L and 40.7 ug/L in PW-11(shown as MAFR Well-11), and a perchlorate concentration of 5.52 ug/L in PW-13 (shown as MAFR Well-13), an other on-site facility drinking water supply wel1.[FN8: Id.]

At Kirtland Air Force Base, data collected in 2004 show perchlorate contamination in Well #17, a drinking water supply well, at 12.6 ug/L.[FN9: Letter from Carl J. Lanz, Chief, Restoration Section, Kirtland Air Force Base, to Sandra Martin, Chief, Hazardous Waste Bureau, N.M. Environment Dep't (Mar. 31, 2004).] Kirtland is located adjacent to the City of Albuquerque, which is the State's largest metropolitan area having a population over 500,000. Yet there is very little available data on perchlorate in drinking water on and around Kirtland.

The GAO also reported perchlorate contamination in the municipal drinking water supply for the City of Deming, New Mexico at 20 ug/L, and for the City of Des Moines, New Mexico at 5 ug/L. GAO reported perchlorate in the drinking water supply for the City of Clovis, New Mexico, operated by the American Water Company, at 7 ug/L. GAO also reported perchlorate in the water supply for the community of Mountain View Albuquerque, in the South Valley of Albuquerque, New Mexico, at 5 ug/L.

The Environment Department has gathered additional data demonstrating widespread perchlorate contamination in groundwater at several military installations and nuclear weapons facilities throughout the State. In many cases, this contamination threatens present and future drinking water supplies.

At Los Alamos National Laboratory, perchlorate contamination has been monitored in groundwater beneath much of the 40-square mile facility. Of particular significance, sampling conducted beginning in 2005 shows perchlorate concentrations ranging between 30 ug/L and 256 ug/L in intermediate wells located in Mortandad Canyon. More recent data shows that this contamination has remained relatively constant. A deeper monitoring well, Well R-15, shows a perchlorate concentration of 7 ug/L. The highest contamination, 256 ug/L in intermediate well MCOBT-4.4, is within 2000 feet from PM-5, a municipal drinking water production well for Los Alamos County. Low concentrations of perchlorate, below 1 ug/L, have been detected in PM-5. Neither the sources of the perchlorate contamination, nor the nature and extent of the perchlorate plume, are fully characterized. The perchlorate contamination threatens the Los Alamos County water supply, which serves approximately 20,000 people.

At Sandia National Laboratories, adjacent to the City of Albuquerque, perchlorate has been found in the EOD Hill monitoring well at concentrations ranging from 680 ug/L to 4300 ug/L. Data from 2006 and 2007 show that perchlorate has been detected in CYN-MW6 monitoring well at concentrations between 6.56 ug/L and 8.93 ug/L. Perchlorate data at Sandia is limited, however.

At the United States Army White Sands Missile Range, near Socorro, New Mexico, high levels of perchlorate contamination in soil and groundwater is widespread. In 2000, perchlorate was detected in 22 of 23 groundwater monitoring wells at concentrations ranging from 5 ug/L to 21,000 ug/L.[FN10: N.M. Environment. Dep't, Perchlorate Survey 2001 Final Report, vol. 2, tab "White Sands" (unpublished compilation).] Currently, the highest concentrations are 19,000 ug/L. The Army has vigorously resisted conducting any corrective action to remedy the contamination.

At Holloman Air Force Base, groundwater data collected in September 1999 showed perchlorate levels of 15.5 ug/L in monitoring well NM-39-02-01, 15.2 ug/L in monitoring well NM-39-02-02, and 38.9 ug/L in monitoring well NM-39-03.

At Kirtland Air Force Base, data collected in 2006 showed perchlorate levels in monitoring well KAFB-2622 at 8.4 ug/L, and in monitoring well KAFB-2624 at 11.0 ug/L. Data collected in 2008 showed perchlorate in the "School House Mesa Well" at 5.19 ug/L. Yet very little groundwater monitoring data has been obtained for perchlorate at Kirtland.

Comment: 9. Your letter asserts that in the absence of a federal MCL, high perchlorate levels in drinking water will go undetected and therefore national monitoring is needed.

The use of Unregulated Contaminant Monitoring Rule (UCMR) sampling data for regulatory determinations is well established. The nationally- representative UCMR 1 results show that perchlorate does not occur frequently or at levels of public health concern in public water systems. Additionally, as evidenced by more recent sampling results from Lake Mead, the Las Vegas Wash, and the Metropolitan Water District of Southern California (MWD), perchlorate levels continue to decline since the time of the UCMR 1 sampling. The preliminary determination assumes that the concentrations measured in the UCMR 1 survey are still occurring. In fact, levels in many of the highest reported drinking water systems have significantly declined due to source control.

Response: Please see the response to comment ID 28755 in comment code 3300.

Comment: Comments on interpreting occurrence data - Because many states do not have significant occurrence of perchlorate and some had no occurrence, states are concerned that the burden of a possible rule would fall heavily on these states and their water systems with little actual reduction in health risk for their water consumers. ASDWA is also familiar with new data from Nevada (submitted separately) that indicate a reduction in perchlorate levels since the UCMR data were collected. These data need to be included in the analyses along with the modeling approach and use of census data that are addressed in the specific questions.

Response: EPA acknowledges the commenters concern for a federal perchlorate regulation and that some states had no occurrence during UCMR1 monitoring; EPA analyzed additional occurrence data received along with UCMR data (which is the best available and most extensive nationally representative occurrence database for perchlorate in public water systems known to date) and using the criteria mandated by the 1996 SDWA Amendments, determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. See response to comment code 6120. When EPA proposes a NPDWR that includes a maximum contaminant level, EPA will analyze and consider both the costs and benefits that would result from regulation and present these analyses for public comment. See SDWA section 1412(b)(3)(C).

Comment: September 18, 2009 Attention: Docket ID Number EPA HQ-OW-2009-0297 EPA Docket Center Mailcode: 2822T Environmental Protection Agency 1200 Pennsylvania Ave., NW Washington, DC 20460

Dear Environmental Protection Agency:

The Metropolitan Water District of Southern California (Metropolitan) is submitting comments on U.S. Environmental Protection Agency's (EPA) Drinking Water: Perchlorate Supplemental Request for Comments (74 Federal Register 41883). This EPA notice follows the previously proposed action by the EPA not to regulate the drinking water contaminant perchlorate which will affect how state and local officials can respond to localized perchlorate contamination.

Background on the Southern California Situation

Metropolitan is a regional water supply agency that provides supplemental water to nearly 19 million people throughout the southern California area. Our major source of supply, the Colorado River, suffered significant contamination from industrial production of perchlorate for solid rocket fuel and subsequent improper disposal methods. Perchlorate-contaminated groundwater seeping into Lake Mead through the Las Vegas Wash found its way into the Colorado River, which supplies southern California and other downstream users. Levels as high as 20 parts per billion (ppb) were detected in Lake Mead and levels as high as 9 ppb have been detected at the intake to Metropolitan's conveyance system, located approximately 160 miles south of the Las Vegas Wash.

In 1997, the source of perchlorate contamination in the Colorado River was traced to a chemical manufacturing facility formerly owned by Kerr-McGee Corp., and now owned by Tronox, Inc. Tronox, previously a chemical subsidiary of Kerr- McGee, has assumed the responsibility of the ongoing perchlorate remediation activities in Henderson, Nevada. Another large perchlorate groundwater plume is also present in the Henderson area from a second industrial site, and although not known to have reached Las Vegas Wash yet, remediation activities are ongoing for cleanup of that plume by American Pacific Corporation.

Following the detection of perchlorate in the Colorado River, Metropolitan, along with the EPA and agencies in Nevada including the Nevada Division of Environmental Protection (NDEP), organized the forces necessary to successfully treat and decrease the sources of perchlorate loading. Under NDEP oversight, remediation efforts began in 1998 and the treatment operations became fully operational in 2004. These efforts have reduced perchlorate loading into Las Vegas Wash from over 1,000 lbs/day (prior to treatment) to 60-90 lbs/day since early 2007. These have resulted in over 90 percent reduction of the perchlorate loading entering the Colorado River system.

Perchlorate levels in Colorado River water at Lake Havasu have decreased significantly in recent years from a peak of 9 ppb in May 1998 as a result of aggressive clean-up efforts at Henderson, Nevada (see Figure 1). Levels have remained less than 6 ppb since October 2002, and have been generally less than 2 ppb since June 2006.

Figure 1. Declining Perchlorate Levels at Lake Havasu [see PDF docket ID EPA- HQ-OW-2009-0297-0496]

Response: Please see response to comment code 3300.

EPA Comment Code: 3300

Comment: On January 12, 2009, Tronox filed for Chapter 11 bankruptcy protection (U.S. Bankruptcy Court, Southern District of New York). The company cited the significant environmental liabilities taken on from Kerr-McGee as a primary cause of its financial liabilities. Tronox has indicated plans to restructure the company while continuing its operations. Metropolitan is concerned that the outcome of the bankruptcy proceedings could potentially impede or even reverse the ongoing cleanup efforts aimed at remediating perchlorate contamination entering the Colorado River. If perchlorate treatment in the Las Vegas Wash area were discontinued, modeling results suggest that perchlorate levels in the Colorado River could spike to concentrations as high as 9 ppb in as little as 18 months. This level of perchlorate would result in non-compliance by drinking water utilities with California's existing MCL for perchlorate of 6 ppb.

While the State of California does have a 6 ppb MCL for perchlorate, this drinking water standard is not enforceable outside the State. EPA's role in establishing and enforcing a national drinking water standard for perchlorate will be critical in the long-term remediation of perchlorate contamination in

the Colorado River and hundreds of U.S. Department of Defense sites around the country. Since the detection of perchlorate contamination throughout the southwest region and in hundreds of local groundwater wells, Metropolitan, its member agencies, and the drinking water community have called on the EPA to make a regulatory determination on perchlorate consistent with the tenets of the Safe Drinking Water Act. Metropolitan believes that the unique factors surrounding regional perchlorate contamination in the Colorado River system need to be considered.

Response: The commenters concerns regarding the outcome of the bankruptcy proceedings are outside of the scope of this action. Regarding your comment that EPA "make a regulatory determination on perchlorate consistent with tenents of the Safe Drinking Water Act," using the criteria mandated by the 1996 SDWA Amendments, EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. See response to comment code 6120.

EPA Comment Code: 3300

Comment: Additionally, Metropolitan would like to suggest that EPA take the additional time necessary to review and quantify occurrence data collected by the Agency and by individual states including California to better represent possible exposure and occurrence. Perchlorate occurrence is expected to increase unlike other contaminants on the Contaminant Candidate List such as pesticides that are no longer in use.

Response: Please see the response to comment code 3300.

Commenter Name: Tom Porta

EPA Comment ID: 28755
EPA Comment Code: 3300

Comment: The Lower Colorado River System provides drinking water to approximately 26 million residents of Nevada. Arizona, and California through three primary diversions:

1) Southern Nevada Water Authority (SNWA) and Black Mountain Inc. Intakes in Lake Mead, which serve approximately 2 million residents within the Las Vegas Valley (distributed through portions of the City of Las Vegas, the City of Henderson, and Clark County);

2) The Central Arizona Project (CAP) canal, which conveys water from Lake Havasu (near Parker Dam) to several locations throughout Arizona including the Phoenix and Tucson Valleys and serves approximately 5 million residents of Arizona; and

3) The Colorado River Aqueduct operated by the Metropolitan Water District (MWD) of Southern California to convey water from Lake Havasu (near Parker Dam) to several communities in southern

California including several within the greater Los Angeles area and the greater San Diego area. We understand that MWD serves approximately 19 million end users through various wholesale and retail agreements. We also understand that water quality measurements collected and posted by MWD for the Colorado River Aqueduct are tracked under "Whitsett Intake".

Additionally, the Colorado River System also is used for irrigating much of the nation's vegetable crops grown in the Imperial Valley of California and the Yuma, Arizona area. This water is conveyed through the All American Canal from a diversion near Yuma, Arizona to numerous locations in southern California near the US / Mexico International border.

Remediation of perchlorate source areas within the Las Vegas Valley has substantially reduced (by approximately 90 %) the amount of perchlorate entering the Colorado River System (NDEP, 2009c). Corresponding water quality improvements have been realized along the entire southern reach of the Colorado River extending from Lake Mead, though Lake Mohave and Lake Havasu, to the US/Mexico International border. Data collected by numerous entities (i.e., NDEP, SNWA, MWD, CAP, EPA, and others) since approximately 1997/1999 though current have documented the improvements in water quality throughout the lower Colorado River System. The reductions in perchlorate entering the Colorado River System can be observed in the graphs of perchlorate data provided in Appendix A [See PDF docket ID EPA-HQ-OW-2009-0297-0639] and Appendix B [See PDF docket ID EPA- HQ-OW-2009-0297-0640] and are attributable to several successive remediation events including (NDEP, 2009d; NDEP, 2009c):

* initial Seep capture by Kerr McGee (now Tronox) in 1999; * construction of a slurry wall and extraction well field in 2001; * operation a full-scale groundwater treatment system in 2002; * expansion of the Seep area extraction well field in 2003; * transition from an ion exchange system to Fluidized Bed Reactor (FBR) treatment system in 2004; * continued operation and optimization of the FBR and well fields from 2005 through current; * initial installation of an In-situ Bioremediation (ISB) system by AMPAC in 2005; * initial start-up and operation of the ISB system in 2006; and * continued operation and optimization of the ISB system from 2007 through current.

The referenced reduction in perchlorate mass loading to the Colorado River system (via the Las Vegas Wash, a tributary to Lake Mead) were immediately recognized following the initial Seep capture and treatment using disposable ion exchange (IX) resin implemented by Kerr McKee (Tronox) in late 1999. The mass loading values dropped approximately 40% from approximately 900 - 1,000 pounds per day to approximately 500 - 600 pounds per day by December 2001 as can be seen on the "Perchlorate Loading 12-Month Rolling Average" graph in the NDEP maintained Northshore Road data set in Appendix c [See PDF docket ID EPA-HQ- OW-2009-0297-0641] (NDEP, 2009b). Continuous reductions in perchlorate mass are seen in the Northshore Road data beginning with operation of the full-scale remediation system in October 2002. The decrease in perchlorate mass loading continued through conversion to an FBR system in October 2003 and its one-year shake-down period. Decreases in perchlorate mass loading have continued from late 2004 through the present, as Tronox optimized their remediation system and AMPAC initiated remediation of a second perchlorate plume in mid 2006 as can be seen on each of the three data graphs for the Northshore Road dataset in Appendix A [See PDF docket ID EPA-HQ-OW-2009-0297-0639] (NDEP, 2009d). Greater than 90% decrease in mass loading has been sustained since February 2007 (i.e., for more than two and one half years) as can be seen in the Northshore Road tabular data presented in Appendix C [See PDF docket ID EPA-HQ- OW-2009-0297-0641] and the related Breakthrough Curve in Appendix D [See PDF docket ID EPA-HQ-OW-2009-0297-0642]

(NDEP, 2009b; NDEP, 2009a; McGinley & Associates, 2003). These trends are expected to continue.

Water quality improvements within the Colorado River system are documented within the Southern Nevada Water Authority (SNWA) intake data for Lake Mead as can be seen in the Perchlorate Monthly Stream Report provided in Appendix E [See PDF docket ID EPA-HQ-OW-2009-0297-0643] (SNWA, 2009a). Yearly average SNWA Intake data for one of the two existing intakes in Lake Mead show a precipitous drop in perchlorate concentrations from approximately 13.4 ug/L in year 2000, through approximately 10 - 11 ug/L during years 2001, 2002, and 2003, to approximately 2 - 2.5 ug/L in years 2007, 2008, and 2009 as can be seen in the Perchlorate - Yearly Average - AMSWTF Raw Water graph and tabular data provided in Appendix F [See PDF docket ID EPA-HQ-OW-2009-0297-0644] (SNWA, 2009b). These water quality improvements correspond to the significant reduction in perchlorate mass loading to the Colorado River System via the Las Vegas Wash.

Seasonal water quality fluctuations that are present in the Lake Mead data are a result of seasonal lake stratification and mixing events as can be seen in the graph of Saddle Island Intake Data in Appendix E [See PDF docket ID EPA-HQ- OW-2009-0297-0643] (SNWA, 2009a). Lake Mead typically destratifies annually due to changes in temperature and wind driven mixing. The surface waters routinely mix to a depth of 30 - 45 feet below the lake surface level throughout the summer (that allows for stratified water quality conditions) and the surface layer deepens to 100 feet in the autumn. The lake destratifies in the late winter, resulting in more uniform water quality as constituents are dispersed throughout the water column. Therefore, water intake structures (including those at Hoover Dam) will be subject to the water quality present within the water column adjacent to the intake structure and this water quality will change seasonally.

Water quality improvements are also noticeable within the NDEP maintained Willow Beach data set provided in Appendix G [See PDF docket ID EPA-HQ- OW-2009-0297-0645] (NDEP, 2009c). These data were collected from the Arizona side of the Colorado River within Lake Mohave approximately 11 miles downstream of Hoover Dam (Lake Mead). It is thought that these data represent mixed water quality conditions applicable to downstream users. Review of these data shows that perchlorate concentrations have been sustained at less than 4 ug/L, from June 2004 through current as can be seen on the graph of perchlorate concentration and tabular data provided in Appendix G [See PDF docket ID EPA-HQ- OW-2009-0297-0645] (NDEP, 2009c).

Water quality trends at the Metropolitan Water District (MWD) of Southern California Whitsett Intake also show improved water quality over time, with sustained perchlorate concentrations at less than 4 ug/L from June 2004 to November 2005 and less than 2.3 ug/L from November 2005 through present as can be seen in the MWD Whitsett graphical and tabular data provided in Appendix H [See PDF docket ID EPA-HQ-OW-2009-0297-0646] (MWD, 2009). These sustained declines in perchlorate concentrations led to several actions by MWD including:

* Lowering of the reporting (detection) limit from 4 ug/L to 2 ug/ L in September 2003; * Change in analytical methods to EPA Method 331 in January 2007 and EPA Method 332 in July 2008 to permit a 0.1 ug/L reporting limit; and * Change in sample frequency from monthly to quarterly in January 2007. [bullets corrected based on docket ID EPA-HQ-OW-2009-0297-0649]

Similar water quality trends are reported by the Central Arizona Project (CAP) for perchlorate concentrations measured in CAP Intake water near Lake Havasu, Arizona. The similar water quality results reported from MWD and CAP are a result of both entities drawing source water from the same reservoir (Lake Havasu) near Parker Darn, Arizona.

Response: Thank you for providing additional data on the occurrence of perchlorate. EPA acknowledges that there may be sources that had detected perchlorate from UCMR1 monitoring that are either no longer being used or are being treated; however, the 1996 amendments to the Safe Drinking Water Act require the Agency to consider the best available, peer reviewed science when developing drinking water standards. In applying these principles, "best available" usually refers to the availability at the time an assessment is made. UCMR data is the most extensive nationally representative occurrence data for perchlorate in public water systems; therefore, EPA analyzed this data and additional occurrence data in making a regulatory determination for perchlorate. However, there will be another opportunity to consider new data during development of a proposed NPDWR for perchlorate.

Comment: NRDC Response: Only Massachusetts has finalized a drinking water standard for perchlorate; California and New Jersey have not.

As noted in the Federal Register notice, one commenter incorrectly suggests that the population exposed would be capped because of regulatory limits in Massachusetts, California, and New Jersey. As a matter of fact, only Massachusetts has promulgated an MCL of 2 ppb for perchlorate in drinking water. California has set an unenforceable public health goal of 6 ppb.[FN63: California Office of Environmental Health Hazard Assessment, Public Health Goal for Perchlorate. See e.g. http://oehha.ca.gov/public_info/facts/Perchloratefacts.html.] New Jersey has proposed, but has not finalized, an enforceable standard of 5 ppb.[FN64: New Jersey Department of Environmental Protection, New Jersey Register, March 16, 2009 http://www.state.nj.us/dep//rules/notices/031609a.html]

Response: In July 2006, Massachusetts set an Maximum Contaminant Level (MCL) of 2 µg/L and in October 2007, California set an enforceable MCL of 6 µg/L. New Jersey proposed an MCL of 5 µg/L in April 2009 but has not finalized it.

Comment: Occurrence Analysis

USEPA seeks information on the occurrence of perchlorate at concentrations below the MRL of 4 ug/L in the Unregulated Contaminant Monitoring Rule (UCMR) studies. In studies conducted by NJDEP between 2003 and 2005, subsequent to UCMR sampling, the laboratory was able to achieve a MRL of 1 ug/L or lower using EPA Method 314.0. In this study, community and non-community public water systems were chosen based on their potential vulnerability to perchlorate contamination. Reasons for sampling included proximity to military installations and unexploded ordnance, and proximity to previous UCMR-tested sites that showed perchlorate detections; a few of the individual public wells that had tested high in the original UCMR sampling were sampled. Most, but not all, of these samples were taken before treatment. A small number of these were point of entry (POE) samples. Perchlorate was detected in 11 of the 67 public water systems tested at 1 ug/L or above (NJDWQI, 2005).

Response: Please see the response to comment code 3300.

Commenter Name: Anila Jacob
Commenter Organization: Environmental Working Group (EWG)
EPA Document ID: EPA-HQ-OW-2009-0297-0499
EPA Comment ID: 28934
EPA Comment Code: 3300

Comment: In 2005, EWG published findings from a national analysis of tap water contamination based on data provided by public water suppliers from seven states, including Texas and California (EWG 2005). In our analysis, perchlorate levels above the level of quantification were considered significant; we found that over 26 million people in these seven states were served by water systems that had at least one perchlorate detection. Since this data was gathered from only seven states, we expect that the actual number of people in all 50 states who are served by public water systems with at least one perchlorate detection would be much higher.

EWG recommends that the agency consider any perchlorate detections above the level of quantification as significant; this would give a more accurate picture of the number of U.S. residents who are actually drinking perchlorate contaminated water.

Response: Please see response to comment code 5220. Also, see response to comment code 3300.

EPA Comment Code: 4000 Evaluation of Perchlorate Exposure from Sources Other than Drinking Water

EPA Comment Code: 4000

Comment: Moreover, APWA supports EPA's assessment that additional investigation is necessary to ascertain total human exposure and health risks of perchlorate and MTBE before a preliminary determination may be made regarding these chemicals. Finally, we agree that it is important for the Agency to try and identify data that can be used to estimate the contribution of perchlorate exposure from food versus drinking water and we feel as though the urinary bio-monitoring approach is appropriate.

Response: EPA agrees with the commenter and has refined its urinary biomonitoring approach to apportioning perchlorate exposure between food and water.

Comment: USE OF ALTERNATIVE APPROACHES WOULD ENABLE EPA TO MAKE A DETERMINATION ON PERCHLORATE WITH GREATER SPEED AND SCIENTIFIC CERTAINTY

In its Support Document, EPA presents a number of alternatives for evaluating the third statutory criterion, of "meaningful opportunity for health risk reduction" for perchlorate.[FN4: US EPA Regulatory Determinations Support Document for CCL2, May 2007 [hereinafter, CCL 2 Support Document].] Many of these approaches take advantage of the extensive scientific information available on perchlorate.

EPA outlines several options in its Support Document for using the superior biomonitoring data for its regulatory determination. Clearly, real-time human data can be uniquely valuable and would enable EPA to make a determination on perchlorate with greater speed and scientific certainty. Using such powerful new data, EPA can make a determination more quickly and with more scientific certainty than was possible in the past. The National Health and Nutrition Examination Survey (NHANES) biomonitoring data provides a more reliable estimate of total perchlorate exposure in the US population than the fallback of extrapolating from food data.[FN5: Benjamin C. Blount et al., Perchlorate Exposure of the US Population, 2001-2002, J. Expos. Sci. Envtl. Epidemiol., Oct. 2006 [hereinafter Blount 2006c].]

The biomonitoring data demonstrates that total perchlorate exposure from all sources is below the EPA's health benchmark for virtually all US residents. Since drinking water exposure is a small subset of total exposure, it follows that reducing this small subset by a small amount through regulation will not meet the meaningful risk reduction criterion of the Safe Drinking Water Act.

There are two additional approaches that merit Agency consideration, further suggesting that drinking water perchlorate levels pose no meaningful risk to human health. One approach posits that it is unnecessary for EPA to adjust for total exposure because Greer et al.[FN6: Monte A. Greer et al., Health Effect Assessment for Environmental Perchlorate Contamination: The Dose Response for Inhibition of Thyroidal Radioiodide Uptake in Humans, Envtl. Health Perspectives, Sep. 2002, at 927.] and other studies relied on by the NAS panel are studies of total exposure. The last approach posits that EPA could consider the comparative effect on iodine uptake inhibition (IUI) of perchlorate exposure in drinking water to other dietary goitrogens in determining whether there is meaningful opportunity for risk reduction.

In Attachment 2 [See PDF of docket ID EPA-HQ-OW-2007-0068-0168], we discuss the supplemental or alternative approaches that EPA can adopt to directly answer the question of whether regulation of perchlorate in drinking water will result in meaningful reduction in human health risk.

Response: EPA agrees that biomonitoring offers some unique advantages with this type of contaminant which is not metabolized and excreted via urine (and milk in lactating women). The limitation in the use of NHANES is it addresses ages 6 and above.

However, EPA disagrees that biomonitoring data demonstrates that total perchlorate exposure from all sources is below the EPA's health benchmark for US residents. The effect of additional perchlorate added via water in the Greer et al. study over the amounts in food and other iodine inhibitors in food was reflected in the RfD. It is unknown whether the background levels of inhibitors altered the shape of the dose response curve to either lessen or increase the dose of perchlorate required to detect iodine uptake inhibition in the subjects. We presume a straight line i.e., that regardless of the background in the subjects, the incremental additional perchlorate required was 0.07 ug/kg/day to arrive at the NOEL for the additional perchlorate. Given that this notice regards whether or not to regulate perchlorate in drinking water, allowing a normal background of goitrogens in the subjects' diets reveals the additional amount in water needed to produce inhibition. It could be argued that apportionment between food and water has already taken place since this is not total perchlorate, but added water over and above the food. Because these variables are unknown outside of a sequestration study where precise amounts of perchlorate from all food and water is measured, EPA assumes additional perchlorate from any source, food or water, produces the iodine uptake inhibition reflected by the RfD.

Regarding the comment that EPA could consider the comparative effect on iodine uptake inhibition of perchlorate exposure in drinking water to other dietary goitrogens in determining whether there is meaningful opportunity for risk reduction, EPA believes that the approach has merit; however, a cumulative risk assessment would require significant new data collection and would unnecessarily delay regulatory decision making for perchlorate. The Administrator will make regulatory determinations on a case-by-case, contaminant specific basis. In making a regulatory determination, the Administrator considers the adverse health effect of the particular contaminant at issue as well as the occurrence or likelihood of occurrence of the contaminant in public water systems with a

frequency and at levels of public health concern. Finally, it is the sole judgment of EPA's Administrator to determine whether there is a meaningful opportunity to reduce health risk for persons served by public water systems.

EPA Comment Code: 4000

Comment: After reading the EPA report, it is clear the EPA did not consider the fact that perchlorate is concentrated many times (19X was cited) in lettuce, which is watered in California by perchlorate contaminated water. Studies of perchlorate concentrations in lettuce found in supermarkets across the US finds high concentrations of perchlorate in lettuce, which is usually grown in California. The EPA study did not utilize this information in its findings. Until the EPA allows this information into its deliberations, their study, and findings, are not complete. DOD has effectively blocked the lettuce findings, and President Bush has refused to allow the EPA to conduct further studies, saying we are at war, which protects DOD from the costs of clean-up. If the reader would consider his or her own family, women would probably be found taking Synthroid due to thyroid issues. Might the fact that women tend to eat more salads than men correlate? None of these issues are addressed by the EPA.

Response: Leafy vegetables do concentrate salts such as perchlorate as water evaporates from leaves (evapotranspiration). EPA has evaluated early studies of perchlorate content of food and reported these findings in the May 1, 2007 Federal Register notice. The data from FDA's total diet study as well as biomonitoring studies by EPA/CDC have further refined the contribution of food to perchlorate exposure in various age/sex groups as discussed in the October 10, 2008 and August 19, 2009 notices. EPA does not believe that the widespread presence of perchlorate in food overrides the need for public health risk reduction for persons served by PWSs with perchlorate contamination. EPA recognizes that a drinking water regulation would not eliminate total perchlorate exposure, but believes that the reduction in perchlorate exposure in drinking water presents a meaningful opportunity for health risk reduction for persons served by PWSs contaminated by perchlorate.

EPA Comment Code: 4000

Comment: EPA's analysis fails to consider that the combination of food and drinking water exposure to perchlorate in the U.S. population exceeds the reference dose set by EPA. Nor does it incorporate the more protective methodology behind the recent state regulatory actions. These flaws must be remedied for the sake of the millions of U.S. families exposed to dangerous levels of perchlorate contamination.

Response: EPA considers the combination of food and drinking water through the relative source contribution (RSC). The RSC is the percentage of the reference dose remaining for drinking water

after other sources of exposure to perchlorate have been considered (e.g., food). See the August 2009 Federal Register notice (41887) for a detailed discussion of RSC derivation.

Regarding the comment about incorporating methodologies behind recent state regulatory actions, States use different methodologies or assumptions to derive their own standard based on their unique exposure scenarios. EPA has used the best available peer reviewed science in making this regulatory determination.

EPA Comment Code: 4110 Dietary studies – FDA's 2005-2006 total dietary study (TDS)

Individual Comments

EPA Document ID: EPA-HQ-OW-2008-0692-1987
EPA Comment ID: 20976
EPA Comment Code: 4110

Comment: FDA's Food Sampling Results Reveal that Perchlorate Concentrations are Below the Level of Concern and that Iodine intake Actually Exceeded NAS-Recommended Levels for all Groups Across the US Population.

When perchlorate was first discovered in food, the FDA began sampling produce and bottled water in an effort to characterize perchlorate occurrence in food. FDA later expanded its perchlorate sampling effort to include other vegetables, fruits and milk to gain a greater understanding of the range of foods that contain perchlorate. FDA's efforts included a total dietary survey (TDS), the results of which were provided to US EPA for use in determining total perchlorate exposure in the US population.

TDS is a market basket survey of various foods analyzed for perchlorate and iodine, conducted by FDA from 2003-2006. In early 2008, FDA published its testing results for 285 food samples in each of three cities in each of the four regions of the country. FDA evaluated the food data based upon estimated food consumption patterns of 14 age/sex groups from 6-11 month-old infants up to 70+ year-old men and women.

FDA found that the average daily intake of perchlorate was well below both the NAS RfD and health reference level (HRL). FDA identified children 2 years of age as having the highest average intake of perchlorate at 0.35 to 0.39 ug/kg bw/day, which at the upper end is slightly more than half of the RfD, but still below the HRL.

For iodine, FDA found that each of the 14 age/sex groups, including infants, children, and women of childbearing age exceeded the average intake levels estimated by the NAS to meet requirements for healthy individuals.

In light of these findings, FDA continues to stand by its prior recommendation that consumers should not alter their infants' and children's diets and eating habits. Indeed, many of the foods at issue are major dietary sources of iodine and other nutritionally essential substances.

Response: No response necessary to this summary of FDA TDS information.

EPA Comment Code: 4110

Comment: iii. Murray et al. (2008)

The Food and Drug Administration (FDA) total diet study (TDS) was "designed to monitor the U.S. food supply for chemical contaminants, nutritional elements, and toxic elements." Based on measurements of perchlorate and iodine in market baskets, the Murray et al. report estimated intake doses. The sampling approach is based on "market baskets" that are collected four times per year. Each market basket contains 285 foods, collected simultaneously in three cities within a region. The modeled group estimated to have the greatest dietary exposure to perchlorate was children age 2 (0.35 to 0.39 ug/kg-day). This is due to the high intake of dairy products coupled with low body weight. The modeled dose for the most sensitive population, the fetuses of pregnant women, was not specifically modeled, but the estimated dose for women of child bearing age was 0.09 to 0.11 ug/kg-d.[FN3: The estimated doses for women ages 14-16, 25-30, and 40-45 were all 0.09 to 0.11 ug/kg-d.] Adult men age 25 to 30 years old were estimated to be exposed to 0.08 to 0.11 ug/kg-day. Of the foods measured in this study, spinach, tomatoes, and cantaloupe had the highest levels of perchlorate at 40, 78, and 24.4 ug perchlorate/kg wet weight of food, respectively.

This study can be used to estimate exposures to perchlorate based on actual food concentrations. Even at the highest estimate, this dose was less than the U.S. EPA RfD of 0.7 ug/kg-day. The study does not aim to evaluate overall body steady-state serum concentrations of perchlorate, only dose. Children age 2 have a higher renal excretion rate than adults or infants do, which would reduce their steady-state serum concentration despite the higher intake.[FN4: Perchlorate is a non-metabolized pharmaceutical agent with nearly complete urinary excretion. Data on adult and child clearances is available for other pharmaceuticals making it possible to extrapolate the rate of a child's clearance of perchlorate compared to an adult's. Based on the clearance of gabapentin, gentamicin, isepamicin, ticarcillin, and vancomycin, the clearance in a child is 1.6 times that of an adult (unpublished data).]

Response: EPA does not believe that the widespread presence of perchlorate in food overrides the need for public health risk reduction for persons served by PWSs with perchlorate contamination. The Agency presented an extensive evaluation of dietary exposure to perchlorate in the October 2008 and August 2009 notices (73 FR 60262; USEPA 2008a and 74 FR 41883; USEPA 2009b). EPA has used this dietary exposure data to account for the relative source contribution (RSC) of perchlorate from food. EPA recognizes that a drinking water regulation would not eliminate total perchlorate exposure, but believes that the reduction in perchlorate exposure in drinking water presents a meaningful opportunity for health risk reduction for persons served by PWSs contaminated by perchlorate. Please see response to comment code 5220 for a discussion of EPA's revised approach to deriving potential HRLs.

EPA Comment Code: 4110

Comment: US FDA's Food Sampling Results Reveal that Perchlorate Concentrations are Below any Meaningful Level of Concern and that Iodine Intake Actually Exceeds NAS- Recommended Levels for all Groups Across the US Population.

When perchlorate was first discovered in food, the U.S. FDA began sampling produce and bottled water in an effort to characterize perchlorate occurrence in food. FDA later expanded its perchlorate sampling program to include other vegetables, fruits and milk to gain a greater understanding of the range of foods containing perchlorate. FDA's work included a total dietary survey (TDS), the results of which were provided to US EPA for use in determining total perchlorate exposure in the US population.

The Total Dietary Survey is a market basket survey of various foods analyzed for perchlorate and iodine, conducted by FDA from 2003-2006. In early 2008, FDA published its testing results for 285 food samples in each of three cities in each of the four regions of the country. FDA evaluated the food data based upon estimated food consumption patterns of 14 age/sex groups from 6-11 month-old infants up to 70+ year-old men and women.

FDA found that the average daily intake of perchlorate was well below both the NAS' recommended RfD and USEPA's current 15 ppb health reference level (HRL). FDA identified children 2 years of age as having the highest average intake of perchlorate at 0.35 to 0.39 ug/kg body weight/day, which at the upper end is slightly more than half of the RfD, but still below the HRL.

Response: In the October 2008 preliminary regulatory determination, EPA had derived a single HRL of 15 µg/L based upon the RfD, an estimate of perchlorate exposure from food for pregnant women, and traditional adult body weight (70 kg) and drinking water consumption (2 L/day) values. This single HRL was derived to reflect exposure to a pregnant woman and her fetus, which the NRC identified as "the most sensitive population." Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

EPA Document ID: EPA-HQ-OW-2009-0297-0652
EPA Comment ID: 28680
EPA Comment Code: 4110

Comment: These results, taken together with the results of EPA's 2006 tests of nearly 40,000 water samples from across the U.S.,[FN1: Office of Water: The Analysis of Occurrence Data from the First Unregulated Contaminant Monitoring Regulation (UCMR1) in support of Regulatory Determinations for the Second Drinking Water Contaminant Candidate List (EPA 815-D-06-008);] which show that perchorate levels were less than seven parts per billion in 99% of the samples, provide no evidence that individuals ingest perchlorate at daily doses exceeding the Reference Dose.

They also suggest that there is little likelihood that such exposures would occur. This conclusion is further supported by data from the U.S. Centers for Diseases Control's National Health and Nutrition Examination Survey (NHANES) biomonitoring dataset (see below).

Response: Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination. The CDC NHANES biomonitoring data set does not include data for all life stages.

Comment: July 24, 2007 US Environmental Protection Agency Office of Water Docket (Mailcode 2822T) 1200 Pennsylvania Avenue, NW Washington, DC 20460

RE: Supplemental Comments on Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant Candidate List Rule, Docket ID: EPA-HQ- OW-2007-0068

In May 2007, the US Food and Drug Administration posted a Preliminary Estimation of Perchlorate Dietary Exposure Based on FDA 2004/2005 Exploratory Data on the web at www.cfsan.fda.gov/~news/whatsnew.html. Perchlorate exposure from consumption of 27 foods and beverages was estimated via a Monte Carlo simulation. The Monte Carlo simulation sums perchlorate exposure values based on food intake and perchlorate concentration levels randomly drawn from a range of possible values for each food from a particular iteration to yield a total exposure for an individual. The summary of their analysis is presented in their Table as follows:

[Table. Summary of Population-Based Perchlorate Exposures]

FDA did not consider other dietary goitrogens such as nitrate and thiocyanate in their analysis in order to place these results in perspective. Although thiocyanate is the most significant dietary goitrogen that shares the same mechanism of action as perchlorate, the food content of thiocyanate precursors is not widely reported. On the other hand, the nitrate contents of various dietary sources has been widely reported in the peer reviewed literature and nitrate is known to share the same mechanism of action as perchlorate (competitive inhibition of iodine uptake by the thyroid). Nitrate is known to be approximately 1/240th as potent as perchlorate on a weight ingested basis in the inhibition of iodide uptake (IUI). (Tonacchera et al., 2004)

Due to the data gap, the Perchorate Study Group (PSG) contracted with Kenny Crump and Cynthia Van Landingham of Environ in Ruston, LA to perform a similar Monte Carlo analysis of nitrate consumption to assess the relative importance of these two dietary goitrogens on IUI [See PDF of docket ID EPA-HQ- OW-2007-0168-0170]. Using the relative potencies of nitrate and perchlorate derived from Tonacchera, the nitrate data summaries from Crump & Van Landingham, Table 4 can be compared directly with the perchlorate summaries from FDA in their Table 2. These comparisons are presented below.

[Table 2 See PDF of docket ID EPA-HQ-OW-2007-0168-0170]

Thus, this analysis indicates that dietary nitrate is two to three orders of magnitude more significant than dietary perchlorate in IUI by the thyroid. Controlling dietary perchlorate is thus relatively insignificant to overall thyroid health than is controlling dietary nitrate intake.

Thank you for allowing us the opportunity to submit this supplemental information for consideration by the Agency in making a regulatory determination on perchlorate.

Sincerely, Michael Girard The Perchlorate Study Group

Attach:

[Attachment - see PDF]

Response: EPA considers the combination of food and drinking water through the relative source contribution (RSC). The RSC is the percentage of the reference dose remaining for drinking water after other sources of exposure to perchlorate have been considered (e.g., food). See the August 2009 Federal Register notice (74 FR 41883; USEPA 2009b) for a detailed discussion of RSC derivation. EPA acknowledges that nitrate and thiocyanate have the same mode of action as perchlorate, and that the effects of combined exposure to perchlorate, nitrate, and thiocyanate are additive, EPA does not believe there are sufficient scientific data currently available to assess and characterize the combined risk of these contaminants. EPA has committed to a drinking water strategy that outlines four principles to expand public health protection for drinking water (USEPA, 2010b). One of these principles is to address contaminants as groups. However, EPA does not believe that regulatory action to address perchlorate should be further delayed. Therefore, EPA intends to develop a proposed rule for perchlorate. At such time as a NPDWR is promulgated, EPA is required to review and revise, as appropriate, its drinking water standards at least every six years. Any revision must at least maintain or improve public health protection. When there are sufficient scientific data to assess the cumulative risks of perchlorate and other contaminants, EPA will review this information to evaluate whether any new or revised NPDWRs are appropriate.

Commenter Name: Tom Curtis
Commenter Organization: American Water Works Association
EPA Document ID: EPA-HQ-OW-2008-0692-1424
EPA Comment ID: 20440
EPA Comment Code: 4130

Comment: Since the NRC published its findings in 2005, several studies have been completed that provide data necessary to evaluate; the, population exposure potential. In the study developed by Mendez et.al. (2008), probabilistic (Monte Carlo) simulation was used to estimate the potential contribution of drinking water to the aggregate perchlorate intake by the presumed most sensitive population, reproductive age women. The full report is attached as Appendix A [see PDF Docket ID EPA-HQ-OW-2008-0692-1424] to these comments. Food perchlorate concentration distributions were derived from the FDA 2004-5 Exploratory Sampling dataset. Food and waterconsumption data were obtained from the USDA Continuing Survey of Food Intake by Individuals (CSFII) from 1994-96 and 1998. The Monte Carlo simulation derives three distributions of perchlorate concentrations in drinking water, corresponding to "raw" data from EPA's UCMR1 national perchlorate sampling, data from the UCMR1 with low-level "background" perchlorate concentrations added to a portion of the entry points below detection limits, and UCMR1 data for

large California systems, again with "background" perchlorate concentrations added to a proportion of non-detect observations.

Inclusion of the estimated national drinking water distributions in the simulation resulted in increases in estimated median perchlorate intakes 3-20 percent greater than those seen when only dietary sources were evaluated. The perchlorate intake distributions estimated based on diet and water intake were found to be very similar to the distributions estimated based on perchlorate excretion data from 2001-2002 and 2003-2004 National Health and Nutrition Examination Survey (NHANES) data sets. The intake estimates based on diet and water and estimates derived from urinary excretion analyses suggestthat approximately two to five percent of reproductive age women in the U.S. receive perchlorate intake greater than 2x10-4 mg/kg-day, which is approximately one-third of the RfD for perchlorate. This proportion does not appear to be strongly affected by reasonable assumptions related to background drinking water contamination. The proportion of women with intakes above the RfD (7x10-4 mg/kg- day) cannot be estimated accurately from either the dietary intake analysis or NHANES data because of the sparcity of data in the upper percentiles of the distribution, but is likely to be considerably lower than two percent nationally. In addition, the proportion of women adversely effected by perchlorate exposure is likely to be even lower, since perchlorate appears to adversely effect thyroid function only in women with insufficient iodine intake. (Blountet al. 1996).

This finding, that the total dietary exposure (food and drinking water) of reproductive age women in the U.S. is approximately one-third of the RfD for perchlorate at the 95th percentile, is complimentary to the finding referenced in the proposed decision based on a joint assessment prepared by EPA-CDC. Given this evidence related to limited exposure potentials and estimated intakes well below the RfD it is clear there is limited potential for perchlorate to present a significant adverse affect on the nation's health, including sensitive subpopulations.

Response: EPA disagrees and has decided to regulate perchlorate in drinking water. See response to comment code 6120. EPA estimates that at least 5.1 to 16.6 million people are served by PWSs, for which we have data, that have perchlorate contamination. EPA has determined that a NPDWR for perchlorate could reduce perchlorate exposures for these populations to levels below the potential alternative HRLs that EPA has identified as levels of public health concerns for purposes of this determination, and that such exposure reductions present a meaningful opportunity for the reduction of health risks for persons served by PWSs.

Comment: EPA must also consider other exposure pathways and additional contaminants in the environment that impact thyroid function when establishing the MCL. Studies of perchlorate levels in food, including breast milk, show that the population is exposed through multiple pathways in addition to contaminated drinking water.

Response: See response to comment ID 20289 under comment code 4130. Additionally, EPA does apportion the exposure to perchlorate to food and derived the drinking water allowance considering the portion of the RfD already used by food.

Commenter Name: Robert E. Brackett
Commenter Organization: Grocery Manufacturers Association (GMA)
EPA Document ID: EPA-HQ-OW-2009-0297-0413
EPA Comment ID: 28706
EPA Comment Code: 4130

Comment: GMA is concerned that Environmental Protection Agency's (EPA) approach to assessing potential risks of perchlorate in drinking water will be widely misunderstood and misinterpreted, leading to confusion and unnecessary concern among US consumers, and food importers, global policy makers, and regulatory bodies about perchlorate in US food products. GMA believes that sound public health policy requires that the relevant government agencies, including EPA, send a clear and consistent message to consumers that any hypothetical risks of perchlorate exposure to pregnant women and mothers of infants estimated by EPA are easily avoided by eating iodine-rich foods or taking an iodine supplement. This approach confers the double benefit of decreasing risk of disease associated with inadequate iodine intake as well as mitigating any potential risks of environmental exposure to perchlorate. We will elaborate below.

First, it is important for EPA to be clear with the public that exposure to perchlorate, or to other substances in the diet that may interfere with iodine uptake by the thyroid, is only a potential problem in individuals with iodine deficiency. There is no evidence that iodine deficiency is currently a serious situation in the United States.[FN1: FDA has estimated iodine intake by the US population using data from the Agency's Total Diet Study (http://www/fda.gov/Food/FoodSafety/FoodContaminantsAdulteration/ChemicalContaminants/Perchlorate/ucm077572.htm)]

Based upon common food consumption patterns in the United States, and the availability of iodine within the US diet, only those individuals consuming highly restrictive diets or those deliberately avoiding iodine are at high risk of deficiency. In addition to naturally rich sources of iodine, such as fish and shellfish, iodine can be found in meat, poultry, and dairy products as well as in many manufactured food items including cereals and baked goods. Further, table salt is frequently consumed in an iodized form. Many dietary supplements, including prenatal multivitamin and mineral supplements contain iodine.[FN2: C Fields, M Dourson, J Borak. Iodine-deficient vegetarians: a hypothetical perchlorate-susceptible population? Regulatory Toxicology and Pharmacology 42 (2005):37-46] Despite the fact that data from NHANES I and NHANES III surveys suggested a decline in iodine consumption, data from more recent NHANES analyses show that iodine consumption has stabilized to a median level considered adequate based upon the World Health Organization guidelines for population adequacy.[FN3: KL Caldwell, R Jones, JG Hollowell. Urinary Iodine Concentration: United National Health and Nutrition Examination Survey 2001-2002. Thyroid 15(7) 2005: 692-699] The Institute of Medicine's Food and Nutrition Board Dietary Reference Intake report for iodine concluded that infants under six months of age fed a diet exclusively of breastmilk have adequate and appropriate intake levels to support normal growth and development.[FN4: http://www.nap.edu/catalog.php?record_id=10026] In addition, infant formula manufacturers are required to fortify infant formula sold in the United States with iodine based

upon the Food and Drug Administration's (FDA) infant formula composition regulations found at 21 CFR 107.

There is no evidence of pervasive iodine deficiency in the United States in infants, children or adults. Some populations are hypothetically more at risk for effects of perchlorate consumption, most notably women of child-bearing age and pregnant women. Because of inadequate iodine consumption during pregnancy can lead to negative birth outcomes, any further reduction uptake by the thyroid from exposure to perchlorate could pose a risk. However, there is no evidence of widespread iodine deficiency among women of childbearing age or pregnant women in the United States. Therefore, any potentially susceptible subpopulation could be targeted with interventions such as education about diet during pregnancy and food sources of iodine, or supplementation. Adequate prenatal care should include an evaluation of a women's diet to assess for potential micronutrient deficiencies and appropriate counseling to help women plan their diets to address their changing nutrient needs during pregnancy should be provided.

Response: EPA agrees that promoting iodide nutrition is good public health policy and may have a positive influence in reducing the iodide uptake inhibition effects associated with exposure to perchlorate. However, the Agency does not think it is appropriate to rely on the promotion of iodide nutrition in this case, especially since these activities are outside of EPA's SDWA authority. The three SDWA criteria for a positive regulatory determination have been satisfied. While the health concerns associated with perchlorate may be addressed through other means, it is the Administrator's judgment that a standard limiting perchlorate in drinking water can reduce health risk, particularly to fetuses, infants and children.

EPA Document ID: EPA-HQ-OW-2009-0297-0413
EPA Comment ID: 28708
EPA Comment Code: 4130

Comment: GMA notes with interest the draft review of the EPA perchlorate assessment by the EPA Office of Inspector General (OIG draft)[FN5: http://www.epa.gov/oig/reports/2009/20081230-2008-0010.pdf]. The OIG draft points out that there are other compounds occurring naturally in foods that act in similar ways as perchlorate, and that regulating the perchlorate level in drinking water is therefore unlikely to make any material difference. The best way to protect public health would be to assure that the iodine status of sensitive subpopulations is adequate. As discussed above, there is no evidence that the iodine status of sensitive subpopulations is inadequate, we agree with OIG that promoting adequate iodine intake by the population appears to be a superior approach to regulating perchlorate as a contaminant in public drinking water systems.

Third, GMA is concerned that EPA's approach to assessing potential risks of perchlorate in drinking water will lead to confusion and unnecessary concern among importers of US food products about the potential for perchlorate in commodities and food products exported by the United States. FDA has reported finding perchlorate in targeted monitoring of some foods, and continues to test additional food types for perchlorate to further enhance the assessment of dietary exposure to consumers. EPA's concern is manmade sources of perchlorate, but perchlorate is known to form in the atmosphere and to occur naturally in the environment, notably in certain geographic deposits

mined for fertilizer, the safety of perchlorate in food is scheduled for thorough evaluation on an international basis by the Joint FAO-WHO Expert Committee on Food Additives and Contaminants (JECFA) in 2010.[FN6: Tolerable Daily Intakes (TDIs) established by JECFA form the basis for food standards and maximum residue limits (MRLs) in foods established by the Codex Alimentarius Commission (Codex). Codex was created in 1963 by FAO and WHO to develop food standards, guidelines and related texts such as codes of practice under the Joint FAO/WHO Food Standards Programme. The main purposes of this Programme are protecting health of the consumers and ensuring fair trade practices in the food trade, and promoting coordination of all food standards work undertaken by international governmental and non-governmental organizations (http://www.codexalimentarius.net/web/index_en.jsp).]

In summary, we reiterate that sound public health policy requires the relevant government agencies, including EPA, to send a clear and consistent message to consumers. Any hypothetical risks of perchlorate exposure to pregnant women and mothers of infants as estimated by EPA are easily avoided by eating iodine-rich foods or taking an iodine supplement. This approach will not only mitigate any risk that may be associated with environmental exposure to perchlorate, but will also decrease the risk of disease associated with inadequate iodine intake.

GMA appreciates this opportunity to provide comments on EPA's approaches to the interpretation of the scientific data relevant to a regulatory determination for perchlorate in drinking water. We urge EPA to work in concert with FDA to assure that consumers are given balanced and consistent advice and perspective concerning the theoretical risks of chemical exposures, including risks to sensitive subpopulations. Providing this balance and perspective is particularly critical in the case of chemicals that may occur in foods that are sources of essential nutrients conferring substantial overall net benefits to health.

Sincerely yours, Robert E. Brackett, Ph.D. Senior Vice President and Chief Science and Regulatory Affairs Officer

Commenter Name: Anila Jacob
Commenter Organization: Environmental Working Group (EWG)
EPA Document ID: EPA-HQ-OW-2009-0297-0499
EPA Comment ID: 28932
EPA Comment Code: 4130

Comment: EWG supports the agency's decision to develop HRLs based on life stage and drinking water ingestion rates but we would like to bring attention to some findings from a recent CDC study of infant formula contamination that we believe would change the HRLs for infants six months of age and under. In this study, researchers tested 15 brands of powdered infant formula for perchlorate and found contamination in every brand; the two most contaminated brands, made from cow's milk, accounted for 87 percent of the U.S. powdered formula market in 2000 (Schier et al 2009).

In Table 4 of the CDC study, the researchers estimate the minimum water perchlorate concentration needed to reach the current RfD for infants at one month and six months of age at different body weight percentiles. At the highest perchlorate concentration found in the formula samples (5.05

ug/l), the researchers found the estimated minimum water perchlorate concentration needed to reach the RfD was zero for the following four exposure scenarios:

- One month old infant, 10th percentile body weight - One month old infant, 50th percentile body weight - One month old infant, 90th percentile body weight - Six month old infant, 90th percentile body weight

In fact, in all four of these exposure scenarios, infants would exceed the current RfD from formula consumption even with perchlorate levels at zero in the water used to reconstitute it. A recent GAO report found that by six months of age, less than 30% of infants are exclusively breast-fed (GAO 2006); in addition, powdered infant formulas account for 50 to 60% of the total infant formula market. This means that millions of infants per year may be exposed to powdered infant formula that is so heavily contaminated with perchlorate that formula exposures alone in these infants may exceed the current RfD.

These results suggest that for infants six months of age and younger who are fed powdered formula, there is no safe HRL since any can of powdered formula may be contaminated with perchlorate at high enough concentrations that formula consumption alone results in exposures above the RfD. EWG recommends that the agency incorporate these exposure dosing scenarios from the formula study and modify the HRLs for infants six months and younger to reflect these findings.

Response: EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

Comment: Blount, et al. [FN12: Blount BC, Pirkle JL, Osterloh JD, Valentin-Blasini L, and Caldwell KL. 2006. Urinary Perchlorate and Thyroid Hormone Levels in Adolescent and Adult Men and Women Living in the United States. Environmental Health Perspectives (114)12: 1865-71.] evaluated 2001-2002 biomonitoring results from the National Health and Nutrition Examination Survey (NHANES) looking at urinary perchlorate, urinary iodine, and thyroid hormone levels and determined that total thyroxine (T4) and thyroid stimulating hormone (TSH) levels were related to urinary perchlorate in women. TSH and T4 levels were used as indicators of how well the thyroid was functioning. TSH causes the thyroid gland to produce triiodothyronine (T3) and T4. Both hormones are needed for normal brain development. Perchlorate was a significant positive predictor of TSH in women with urinary iodine >100 ug/l and significant positive predictor of TSH and negative predictor of T4 in women with low urinary iodine (< 100 ug/l). This implies that women and fetuses of women with low dietary intake of iodine can be impacted by perchlorate at current exposure levels in the United States population. This is especially of concern because recent NHANES data show that nearly 17% of reproductive aged women in the United States have urinary iodine levels less than 50 ug/l. The World Health Organization classifies someone as being iodine deficient at a urinary iodine level below 100 ug/l.

Response: EPA agrees that low iodide nutritional status increases the likelihood of negative impacts due to perchlorate.

EPA Comment ID: 20906
EPA Comment Code: 4210

Comment: * EPA presents results from an unpublished study and relies on this study to justify a HRL of 15 ug/L (ppb) for perchlorate in drinking water, although this study does not look at risks to young children or breast-fed infants;

Response: In the October 2008 preliminary regulatory determination, EPA had derived a single HRL of 15 µg/L based upon the RfD, an estimate of perchlorate exposure from food for pregnant women, and traditional adult body weight (70 kg) and drinking water consumption (2 L/day) values. This single HRL was derived to reflect exposure to a pregnant woman and her fetus, which the NRC identified as "the most sensitive population." The study supporting this HRL was made available to the public through the regulations.gov web site and was peer reviewed outside the

Agency. The study focused on the most sensitive life stage available in the data (biomonitoring data are not available for children under the age of 6).

In the August 9, 2009, notice (74 FR 41883; USEPA 2009b), EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information. These potential alternative HRLs are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These potential alternative HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts.

EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

EPA Comment ID: 20914
EPA Comment Code: 4210

Comment: EPA presents new information from unpublished study that does not include young children: In its assessment, EPA presents an unpublished study in which EPA and CDC researchers merged urine perchlorate levels from the NHANES study and water contamination data from the Unregulated Contaminants Monitoring Regulation with the goal being to "derive the dose of perchlorate coming from food alone by eliminating possible sources of water contribution" (EPA 2008). Individuals from the NHANES study were categorized into three groups depending on whether the counties in which they resided were found to have drinking water contaminated with perchlorate or not. Using this approach, EPA was able to estimate daily perchlorate intakes for those with likely perchlorate exposure through drinking water and those without; EPA concluded that "The mean total exposure for people that are more likely to be exposed to perchlorate in food and water was calculated to be 0.101 ug/kg/day. The average exposure for people more likely to be exposed to perchlorate from food alone was 0.090 ug/kg/day" (EPA 2008).

This approach allows EPA to estimate that the population they consider to be most at risk, pregnant women and the developing fetus, can be exposed to perchlorate levels in drinking water as high as 15 ug/L and still not exceed the RfD. The most glaring flaw with EPA's study is that it does not include young children. The FDA research establishes that young children have the highest perchlorate exposures from food and therefore, are most likely to exceed EPA's RfD from additional exposures to contaminated drinking water. The NHANES data does not include information on children under the age of 6 so EPA's study using NHANES data has an enormous data gap which basically invalidates the findings from this study.

Response:
EPA believes that the UCMR-NHANES data merge is valid for the age groups that were represented. The study was peer reviewed outside the Agency and made available to the public through the Regulations.gov web site. EPA has incorporated analyses of these life stages less than

six years of age in the 2009 August Federal Register Notice using data from FDA Total Diet Study to estimate dietary exposure.

Comment: Comment on EPA-HQ-OW-2009-0297

This document gives a detailed review made earlier of the 2006 CDC urinary analysis data. That review raised questions that are still relevant to the discussion of MCL levels for drinking water. In the pages that follow, a number of conclusions can be reached.

SUMMARY AND CONCLUSIONS

1. Perchlorate was detected and quantified in the urine of all 2820 samples tested with a new analytical technique. 50% of those samples exceeded the 4 ppb median value, and 10% of those samples exceeded 10 ppb. That urinary perchlorate could not be explained as coming from water but instead being continually re- supplied by the food being eaten.

2. The correlation of the thyroid T4 hormone with urinary perchlorate as reported by Blount et al. could not be repeated exactly because the sample elimination criteria were insufficiently detailed. A least squares fit to all the data showed less correlation than Blount reported. The scatter plot of the data being correlated deserves as much consideration as correlation coefficients and relevance numbers reported by the statistical analysis. A search for a similar correlation between T4 and nitrate proved negative.

3. Iodide deficiency in women of child bearing age appears to define the population at greatest risk to perchlorate in the drinking water. The percentage of such women appears to be increasing over time, presumably from reduced iodized salt intake being invoked by personal dietary responses to public clamor over excessive salt. A water contaminant specification based on a population that has other means to control its risk but fails to do so is also not appropriate.

4. The effects of thiocyanate and nitrate cannot be ignored. But the levels of those ions in the population at risk also change with time. Reduced smoking in the population, and better control of nitrate runoff into drinking water aquifers will change the effect of those ions over time. Like the changing iodide deficiency over time, it is inappropriate to regulate a contaminant level that will change as the population at risk changes. The conclusions of the OIG report are endorsed.

Respectfully submitted, Richard M. Peekema, retired chemist San Jose, CA

Response: EPA will consider the best available data in evaluating the potential effects of perchlorate and exposure to the public. This includes the study by Blount and others that described their analysis of NHANES data. The findings and limitations of this study have been described in previous federal register notices concerning perchlorate in drinking water.

EPA agrees that perchlorate exposure may result from both food and drinking water. Previous analyses have estimated the portion of the perchlorate exposure from food. EPA considered the portion of perchlorate exposure from food in developing the potential alternative HRLs. See responses to comment IDs 20616 and 20886 under comment code 4000.
Analyses performed by Blount et al. depend upon weighting of subjects with respect to their representation for the population. Without application of appropriate weighting, the analysis cannot be properly reproduced.
EPA agrees that data indicate an increase in the number of women exhibiting low iodide status. However, this is only one of a variety of factors that will be considered in determining whether a NPDWR for perchlorate is warranted. Additional consideration of exposure and developmental stage will also be important factors to evaluate as EPA develops the proposed NPDWR.
EPA received a number of comments that the Agency should consider the comparative effect on iodine uptake of perchlorate exposure in drinking water to nitrate and thiocyanate exposure in drinking water in determining whether there is a meaningful opportunity for risk reduction. EPA's Office of Inspector General (USEPA, 2008c) believes that a NPDWR for a group of chemicals may be appropriate based on a yet-to-be-conducted cumulative risk assessment that assesses and characterizes the combined human health risk from perchlorate, nitrate, and thiocyanate.
While EPA acknowledges that nitrate and thiocyanate have the same mode of action as perchlorate, and that the effects of combined exposure to perchlorate, nitrate, and thiocyanate are additive, EPA does not believe there are sufficient scientific data currently available to assess and characterize the combined risk of these contaminants. EPA has committed to a drinking water strategy that outlines four principles to expand public health protection for drinking water (USEPA, 2010b). One of these principles is to address contaminants as groups. However, EPA does not believe that regulatory action to address perchlorate should be further delayed. Therefore, EPA intends to develop a proposed rule for perchlorate.

Comment: CDC URINE PERCHLORATE ANALYSES

In 2006 the US Center for Disease Control (CDC) released supplemental analyses of urine samples collected for the earlier National Health and Nutrition Examination Survey (NHANES 2001-2002).[FN1: http://www.cdc.gov/nchs/about/major/nhanes/] That new data was based on an improved analysis for perchlorate that was sensitive to 0.05 ppb,[FN2: Valentin- Blasini L, et al.; Anal. Chem. 77: 2475-2481 (2005)] and showed that every one of the participants had measurable levels of perchlorate in their urine.

A statistical analysis of that data by Blount et al.[FN3: Blount BC, et al.; Environ Health Perspect. 114: 1865-71 (2006)] claimed a correlation between very small amounts of perchlorate and reduced thyroid T4 hormones in iodide deficient women. They suggested that extremely low levels of perchlorate could affect the health of such women. The Blount article has been cited as evidence that the MCL of 6 ppb issued by the California Department of Public Health is too high.

The urinary analyses reported by the CDC included more than just perchlorate. Some 2800 individual urine samples were analyzed by the CDC for perchlorate, thiocyanate, nitrate, and iodine. The results of those urine analyses were downloaded from the CDC, copied into a spreadsheet, and are analyzed here to a relatively simple extent. The frequency distribution of the perchlorate concentration is shown in Figure 1, and the cumulative distribution is shown in Figure 3. This population has a median urine perchlorate value of 4.0 ppb and a 10%-90% range of 1.2 - 10 ppb, surprisingly high values.

Figure 1. Distribution of Perchlorate Analysis [see PDF docket ID EPA-HQ- OW-2009-0297-0419]

Figure 3. Cumulative Distribution [see PDF docket ID EPA-HQ-OW-2009-0297-0419]

What is the source of this perchlorate? The biological half life of perchlorate in the body is only eight hours.[FN4: Greer MA, et al.; Environ Health Perspect 110: 927-937 (2002)] That means that every 8 hours, an individual excretes half the perchlorate from his body. Since perchlorate is not detected in about 96% of community water supplies, water cannot be the source of that urinary perchlorate. The detected perchlorate must be coming from dietary intake (vegetables, grains, milk, meat, medication, etc.). The perchlorate intake must be continual or it would soon drop to zero.

T4 HORMONE CORRELATION WITH URINARY PERCHLORATE

Blount's statistical analysis (fn.3) showing a perchlorate-T4 correlation was based on a regression of serum T4 concentrations vs. the logarithm of the urinary perchlorate concentration. (Log[ClO4-] is a normally distributed parameter in the population, while [ClO4-] is not.) The CDC data on urinary analyses yielded 416 female persons of age >=12 years and <100 ppb urinary iodide [the criterion for iodide deficiency] and where T4 data were also available. Blount's correlation cites a sample size of 348, an elimination of 16% of the samples. The referenced article discusses complicated procedures that were used for eliminating samples, but gives few details of those methods.

The results of this analysis here for 416 persons are summarized in the Table 4 below, with a comparison to Blount's numbers. The simple linear regression of the data without sample elimination and weighting shows some but much less correlation than Bount's. Figure 5 is a scatter plot for the perchlorate-T4 analysis using all the perchlorate data with no sample elimination. The line in this figure is calculated from the slope and intercept determined by the least squares fit to the 416 data points.

Figure 5. Correlation of Thyroid t4 with Perchlorate [see PDF docket ID EPA-HQ- OW-2009-0297-0419]

The correlation coefficients in Table 4 show a 10 fold better correlation by Blount than was achieved here. Blount declares his correlation to be statistically significant, but it apparently required extensive sample pruning to achieve those results. Our correlation here is weaker and would probably not be considered statistically significant. The CDC cautions against using their data without taking into account their study design and associated sample weights. When sample weights were incorporated into the frequency distribution, there was a small but not significant difference. With CDC sample weights, the median urinary perchlorate value was projected to be 3.8 ppb for the US population instead of 4.0 ppb for the sample population. However, the simple regression used in Table 4 and Figure 5 could not accommodate sample weights.

Did this analysis confirm Blount's correlation? These results are a limited confirmation of Blount's correlation, but not necessarily of his conclusions. The implied connection between perchlorate and T4 is tenuous at best.

Table 4. Statistical Analyses of CDC Data [see PDF docket ID EPA-HQ- OW-2009-0297-0419]

Attempts here using the released CDC data to demonstrate a similar effect by nitrate were unsuccessful. The results of simple linear regression of T4 levels against nitrate concentration and against log nitrate concentration are also summarized in Table 4 above.

In this analysis, there seems to be no connection between nitrate and T4. All the anion data are for urinary concentrations, whereas the iodide uptake occurs in the serum near the NIS. One might expect perchlorate, which is metabolically inert, to have similar concentrations in serum and urine. On the contrary, nitrate is not equally inert, and there could be sizable differences between serum nitrate and urinary nitrate. That might explain why no nitrate effect was seen.

The truly surprising result of the CDC data is the appearance of urinary perchlorate in every individual tested. Even more surprising is the 4 ppb median value. This can only be explained by food and not contaminated water. Considering the short half life of perchlorate in the body and for discussion assuming no source for it other than water, urinary concentrations are virtually equivalent to drinking water of the same concentration, namely more than 4 ppb for 50% of the population and more than 10 ppb for 10% of the population.

Response: EPA believes that perchlorate exposure may result from both food and drinking water. Previous analyses have estimated the portion of the perchlorate exposure from food. EPA considered the portion of perchlorate exposure from food in developing the potential alternative HRLs. See responses to comment IDs 20616 and 20886 under comment code 4000.
EPA believes that Blount's interpretation of the relationship between T4 and perchlorate concentrations as reported in the peer reviewed literature are authoritative. Blount lists the shortcomings of his analysis in his paper.
EPA does not believe that the widespread presence of perchlorate in food overrides the need for public health risk reduction for persons served by PWSs with perchlorate contamination. The Agency presented an extensive evaluation of dietary exposure to perchlorate in the October 2008 and August 2009 notices (73 FR 60262; USEPA 2008a and 74 FR 41883; USEPA 2009b). EPA recognizes that a drinking water regulation would not eliminate total perchlorate exposure, but believes that the reduction in perchlorate exposure in drinking water presents a meaningful opportunity for health risk reduction for persons served by PWSs contaminated by perchlorate.

Comment: IMPORTANCE OF OTHER ANIONS

Other anions cannot be ignored in assessing the level of perchlorate that sensitive individual can tolerate. The following table summarizes the CDC data released on urinary concentration and the relative potency established for them. Tonacchera et al.[FN5: Tonacchera M, et al.; Thyroid 14:1012-1019 (2004)] have shown perchlorate to be 15, 30, and 240 times more potent than thiocyanate, iodide, and nitrate respectively, for inhibiting radioactive iodide uptake in the Human Sodium Iodide Symporter (NIS). The relative blocking potency values reported by Tonacchera are shown in Table 2.

Table 2. Anion Concentrations & NIS Potency [see PDF docket ID EPA-HQ- OW-2009-0297-0419]

In view of the urinary nitrate concentrations and the NIS potency shown in Table 2 above, one might expect to see a similar correlation between nitrate and the T4 hormone in iodide deficient women. Even though 240 times less potent than perchlorate, nitrate at 53,000 ppb would be equivalent to 221 ppb perchlorate which would have influenced T4. Attempts here using the released CDC data to demonstrate a similar effect by nitrate were unsuccessful. The results of simple linear regression of T4 levels against nitrate concentration and against log nitrate concentration were summarized earlier in Table 4.

Response: Nitrate shares a common mode of action with perchlorate. However, data do not exist at this time to permit a scientifically defensible estimation of the relative potency of perchlorate and nitrate. The Tonacchera paper, an *in vitro* study evaluating the function of human receptors hybridized into animal cells, does not provide sufficient evidence to support a meaningful comparison.

Comment: Finally, other recent studies have demonstrated that perchlorate is actively transported into mammary epithelial cells by the sodium-iodide symporter (NIS), resulting in an accumulation of perchlorate in breast milk.[FN27: Dohan, O, C Portulano, C. Basquin, A Reyna-Noyra, LM Amzel, and N Carrasco. 2007. The Na+/I- symporter (NIS) mediates electroneutral active transport of the environmental pollutant perchlorate. PNAS 104(51):20250-20255.],[FN28: Dasgupta, P. K., Kirk, A. B., Dyke, J. V., and Ohira, S.-I. (2008). Intake of Iodine and Perchlorate and Excretion in Human Milk. Environ. Sci. Technol. 42, 8115-8121.] In fact, in the Dasgupta study, perchlorate was concentrated in breast milk three times more than iodine. Also of note, only one infant out of 13 in this study was found to have adequate iodine intake.

EPA has not adequately accounted for the concentrations of perchlorate in breast milk, the unique susceptibility of breast feeding neonates, or the fact that a significant portion of the U.S. population is iodine deficient, and therefore more susceptible to perchlorate toxicity.

Response: In the October 2008 notice EPA discusses a number of studies that investigated perchlorate in human breast milk including perchlorate concentrations. See response to comment code 2100 for a discussion of EPA's RfD and how that value both accounts for the most sensitive populations who are expose to perchlorate including iodine deficient populations. See response to comment code 5220 for a discussion of alternative HRLs. EPA has examined the relative sensitivity of the breast fed infant as part of its analysis for this regulatory determination as shown in Table 1 of the August 19 2009 Federal Register Notice.

Comment: i. Tellez et al. (2005)

This was a longitudinal epidemiologic study of the effects of environmental perchlorate exposure on the thyroidal status of pregnant women and neonates. Perchlorate is found naturally at high levels in Chilean soils and water supplies. Some have questioned the relevance of this study to the U.S. population as historically, Chile has had high levels of dietary iodide supplementations. However, this supplementation has been decreased to levels that are similar to U.S. levels. In this study, the maternal excretion (and therefore ingestion) of iodine was at levels that were between those reported in NHANES I and NHANES III. The authors measured maternal and neonatal TSH, Tg, and free

T4. They also measured neonatal birth weight, length, and head circumference. They found that "...perchlorate in drinking water at 114 ug/L did not cause changes in neonatal thyroid function or fetal growth retardation." The levels of iodine in breast milk were not associated with perchlorate exposure. The levels of maternal iodine in urine were intermediate to that found in NHANES I and NHANES III and consistent with the World Health Organization (WHO) recommendations. This study strengthens the evidence that the RfD and HRL are conservative health based values.

Response: The data underlying the definition of iodide uptake inhibition as a precursor effect and the relationship of iodide uptake inhibition to the continuum of adverse outcomes may not reflect the relationship of the precursor event to adverse outcomes in children. We know that thyroid hormone status in neonates and infants is less resilient than in adults. That is, in general, neonates and infants may not have iodide stores sufficient to offset the effects of reduced iodide uptake. The less resilient neonatal and infant system makes the exposure gap between a precursor event (iodide uptake inhibition due to perchlorate) and reduced T3/T4 levels likely to be narrower than for adults, and in fact, the distinction between the two may be blurred for the very young (Greer et al., 2002; Savin et al., 2003; van den Hove et al., 1999). The NAS noted that, "[T]he minimal prolonged decrease in thyroid hormone production that would be associated with adverse health effects is not known; any decrease is potentially more likely to have adverse effects in sensitive populations (people with thyroid disorders, pregnant women, fetuses, and infants) but data are not available to determine the magnitude of the decrease needed to cause adverse effects in those populations." See today's Federal Register notice for further discussion of EPA's determination that perchlorate may have an adverse impact on human health.

Comment: ii. Amitai et al. (2007)

This ecological study aimed to "...assess the effect of gestational perchlorate exposure through drinking water on neonatal thyroxine (T4)" by comparing T4 levels among newborns whose mothers lived in areas where drinking water perchlorate levels were very high (>=340 ug/L), high (42-94 ug/L), or low (<3 ug/L). T4 levels were measured within 36 to 48 hours after birth, but there was no comment on whether the infants were breast fed or formula fed during the postnatal period. They found that there were no differences between neonatal T4 levels among the groups. This study provides evidence that the current RfD and values greater are conservative and health protective to the most sensitive individuals in the population.

Comment: C. Breast Milk Studies

For many infants, breast milk is the sole source of food and therefore represents the greatest potential exposure to perchlorate. Although the population theoretically considered the most susceptible to the effects of high levels of perchlorate is developing fetuses, the effects of doses of perchlorate that are sufficiently high to block iodide uptake by the thyroid may alter normal growth and development in infants and children. Taken together, the following studies show that there is no association between environmentally relevant levels of perchlorate in drinking water and perchlorate or iodide in breast milk. Furthermore, no effect, adverse or otherwise, has been found due to environmentally relevant doses of perchlorate.

i. Pearce et al. (2007b)

The objective of the Pearce et al. study was "to determine whether breast milk iodine concentrations in Boston-area women are adequate for infant nutrition, and whether breast milk iodine concentrations may be associated with environmental perchlorate or cigarette smoke exposure." Pearce et al. measured breast milk iodine and perchlorate concentrations as well as iodine, perchlorate, and cotinine in urine. They then compared the levels found in breast milk to 17 commercial infant formulae. Neither breast milk perchlorate nor urinary perchlorate levels were significantly correlated with breast milk iodine concentrations. Although perchlorate was detectable in infant formulae, the levels were lower than that in breast milk. A significant number of women in this study had iodine levels that were insufficient to meet the infant's needs, but the authors did not suggest this was due to perchlorate exposure or that it represents a chronic iodine deficiency.

ii. Kirk et al. (2005)

With the aim to determine what amount of perchlorate children are exposed to, Kirk et al. measured perchlorate and iodide levels in cow and human breast milk and compared these numbers to corresponding levels of perchlorate in drinking water in the area. Perchlorate was measurable in 81 of the 82 samples. The average perchlorate levels in cow milk and human milk were 2 and 10.5 ug/L, respectively. The maximum values of cow and human milk were 11 and 92 ug/L, respectively. There was no correlation between levels of perchlorate in breast milk and perchlorate in drinking water. They speculated that there was a correlation between higher levels of perchlorate and lower levels of iodine in breast milk.[FN7: The Kirk et al study uses an arbitrary and non-scientific method of speculating on this relationship. Kirk et al., write: "...we divide iodide levels [in human breast milk] in two groups, those above 60 ug/L and those below, this being the iodide content for many infant feed formulas"; "we...divide perchlorate content in two groups, high and low, in this case arbitrarily dividing the span of the observed perchlorate range in two equal halves." and "at this point with limited resources, we have been able to analyze only a few samples. Thus, they divide data set using no scientific rationale and then exclude data. The authors state, "If we take all the available data, there is no meaningful correlation between the perchlorate and iodide levels in breast milk."] However, this relationship only existed for the breast milk samples with the highest perchlorate levels (6 subjects out of 82). The authors recognize that this relationship may be coincidental due to the small number of samples with perchlorate levels greater than 10 ug/L, stating that "If we take all the available data, there is no meaningful correlation between the perchlorate and iodide levels in breast milk." As with previous studies, due to the design, this study is not able to evaluate a causal relationship.

iii. Dasgupta et al. (2008)

In a very recently released study, Dasgupta et al. report the results of their study. "The objective of this present study was to study the excretion of perchlorate, thiocyanate, and iodine in milk and urine and relate the observed pattern within the broad framework of parallel / competitive transport by the NIS." Using breast milk and urine samples from 13 lactating women and using EPA default values for infant body weights and milk intakes, the authors mathematically modeled infant intakes and doses of iodide, perchlorate, and thiocyanate. They calculated the fraction of iodide, perchlorate, and thiocyanate in breast milk compared to the total that is excreted in both breast milk and urine. They used a ratio of these fractions in milk to determine the selectivity of either perchlorate or thiocyanate over iodide. They report "that 12 of 13 infants did not have an adequate intake of iodine...and 9 out of 13 infants were likely ingesting perchlorate at a level exceeding the reference dose..." They also concluded that the selectivity of perchlorate over iodide was 3.14 +/- 1.2.

[Text Box: Taken together, studies on perchlorate in breast milk show that there is no association between environmentally relevant levels of perchlorate in drinking water and perchlorate or iodide in breast milk. Furthermore, no effect, adverse or otherwise, has been found due to environmentally relevant doses of perchlorate.]

There are a number of concerns related to the experimental design of this paper. The population is small and there is no information on the selection process of the participants (e.g., they are not a random sample). There are only three biological variables that were measured from these women. The rest of the variables, including the variables used to derive the conclusions, are calculated from these these three in addition to using default values for infant intake and infant weights. The three measurements were the concentrations of of perchlorate, iodine, and thiocyanate in both urine and breast milk. Where other research has measured more biologically relevant information, such as serum concentrations of analytes which would be most reflective of relative concentrations at the NIS (Tonacchara et al., 2004; Pearce et al., 2007) thus, this work is limited. The estimated doses, the key variable for understanding possible NIS effects, are based on average body weight and intakes for an infant of that age with the concentration in breast milk. For such a simple and critical variable, it is suprising that actual body weights were not measured.

In addition to study design, the data presented in this paper appears to contradict the interpretation by the authors of the paper. Based on estimated weights, the authors state that 9 out of 13 infants are consuming daily doses in excess of the RfD. However, from examining Table 1 from Dasgupta et al., there are 8 infants who exceed the RfD of 0.7 ug/kg-d (subjects 1, 2, 8, 11, 13, 15, 16, 20). Furthermore, if one reviews these estimates to measured variables, the infants with estimated perchlorate doses greater than the RfD are also estimated to have the greatest iodine intake. By plotting the values for total iodide excretion (column 4), total perchlorate excretion (column 7), estimated maternal breast milk iodide excretion (equivalent to estimated infant iodide intake; column 5), and estimated maternal breast milk perchlorate excretion (product of total perchlorate excreted and percent of perchlorate in milk; column 7 x column 9) found in Table 1 of the paper, the results demonstrate that perchlorate and iodide are positively correlated (See Figure 3). If perchlorate was inhibiting the transport of iodide into milk, the association would be negative.

[Figure 2: Plotting of data reported by Dasgupta et al., 2008 to illustrate the association between concentrations of iodine and perchlorate in urine and milk in lactating women - See PDF Docket ID EPA-HQ-OW-2008-0692-1855]

In addition to the concerns regarding interpretation of the data presented in this paper, there are concerns about the interpretation of their previous work (Kirk et al., 2005) and how that study impacts this recent study. For example, Dasgupta et al. state in this current paper that "in real mothers perchlorate does inhibit the transport of iodine into milk and because of competitive inhibition both analytes cannot be high at the same time." However, this statement is based on a previous study in which the researchers defined their cut off values[FN8: The cutpoints from Kirk et al. (2005) were defined as follows: High iodide in breast milk was greater than 60 ug/L and high perchlorate in breast milk was greater than 20 ug/L.] above which milk iodide or perchlorate were considered "high." They report that no milk samples had both high perchlorate and high iodide (Kirk et al., 2005). In the present study, they report the same trend although they do not define a cut off value. However, if the previous cut off values are applied to the current study, there are many samples that had simultaneously high perchlorate and iodide (Figure 3). Based on the previous conclusions about competitive inhibition of analytes (Kirk et al., 2005), this study does not demonstrate that perchlorate competitively inhibits iodide transport into milk at the concentrations experienced by these women.

Response: In the October 2008 notice EPA discusses a number of studies that investigated perchlorate concentrations in human breast milk. Poor iodide uptake and subsequent impairment of the thyroid function in pregnant and lactating women have been linked to delayed development and decreased learning capability in their infants and children (NRC, 2005). Additionally, deficiency during childhood reduces child growth and cognitive motor function (Zimmerman, 2009). EPA has considered the portions of the population who are most sensitive to the effects of perchlorate and has determined that perchlorate may have an adverse effect on the health of persons.

Comment: iv. Dohan et al. (2007)

Animal, particularly rodent, studies are an implicit and valuable aspect of toxicology. There are, however, significant differences between human and rodent thyroid physiology. U.S. EPA states, "The fundamental mechanisms involved in the function and regulation of the pituitary-hypothalamus-thyroid system in rats are qualitatively similar to those in humans. However, differences in binding proteins, binding affinities of the proteins for the hormones, turnover rates of hormones, and thyroid stimulation by placental hormones lead to important quantitative differences between the two species. The biochemical and physiologic differences between rats and humans related to the thyroid affect their responses to goitrogens, such as perchlorate. Therefore, although studies in rats provide useful qualitative information on potential adverse effects of perchlorate exposure, they are limited in their utility for quantitatively assessing human health risk associated with perchlorate exposure" (U.S. EPA, 2005).

The main purpose of the Dohan et al. publication is to demonstrate that perchlorate crosses cell membranes via the NIS; to demonstrate perchlorate's ability to be excreted in breast milk; and to develop a mathematical model to characterize their experimental results. The in vitro experiment and system they use is unique, creative, and provides the first evidence of perchlorate crossing a cell membrane using Mardin-Darby canine kidney (MDCK) cells transfected with the human NIS. It provides further evidence regarding questions about breast milk perchlorate levels and whether perchlorate blocks iodide at the symporter or competes against iodide in crossing the NIS. Thus, it decreases uncertainty in the risk assessment process. It is important to remember that this is the first study of its kind, it was conducted in vitro (cell culture), and it was conducted in a non-human cell line with artificially introduced human symporters. From a perspective on cell membrane transport, this work provides qualitative information.

The author's discussion of the in vivo part of the study's relevance to environmental exposures of perchlorate and human health is, however, far reaching and not supported by the results of this experiment. High acute doses of perchlorate were given to the rats. The rats were given an intraperitoneal injection of nearly 8 mg/kg/d in addition to a drinking water exposure of 13.6 mg/kg/d.[FN9: Assumes a 250 g rat with a daily water intake of 5.5 ml/100 g body weight.] The perchlorate doses administered in this study are high enough such that they should effectively block, with complete inhibition, iodide transport by the NIS in these rats, which provides no information about the effects at environmentally relevant doses. The results cannot be used to draw conclusions about what happens from a human health standpoint or mechanistic function at environmentally relevant concentrations.

Response: In the October 2008 notice EPA discusses a number of studies that investigated perchlorate concentrations in human breast milk. In today's notice EPA discusses the uncertainty about the point in the continuum of effects at which adversity occurs, and that these were major considerations in determining whether perchlorate is likely to have an adverse effect on health at a range of life stages. The conclusions of the study by Dohan et al. (2007) that NIS translocates perchlorate in epithelial mammary cells in vivo, based on rat models, represents a valuable contribution to the current scientific literature on the biological mechanisms of perchlorate uptake in mammary cells and its potential inhibitory effect on iodine, and its potential relevance to nursing neonates and infants.

The data underlying the definition of iodide uptake inhibition as a precursor effect and the relationship of iodide uptake inhibition to the continuum of adverse outcomes reflects an understanding of effects in adults; it may not reflect the relationship of the precursor event to adverse outcomes in neonates and infants, who may not have iodide stores sufficient to offset the effects of reduced iodide uptake. The less resilient neonatal and infant system makes the exposure gap between a precursor event (iodide uptake inhibition due to perchlorate) and reduced T3/T4 levels likely to be narrower than for adults, and in fact, the distinction between the two may be blurred for the very young (Greer et al., 2002; Savin et al., 2003; van den Hove et al., 1999). The NRC noted that, "[T]he minimal prolonged decrease in thyroid hormone production that would be associated with adverse health effects is not known; any decrease is potentially more likely to have adverse effects in sensitive populations (people with thyroid disorders, pregnant women, fetuses, and infants) but data are not available to determine the magnitude of the decrease needed to cause adverse effects in those populations."

EPA Document ID: EPA-HQ-OW-2008-0692-1552
EPA Comment ID: 20519
EPA Comment Code: 5000

Comment: Under the Safe Drinking Water Act (SDWA), the EPA considers three criteria to determine if a drinking water standard should be established for a contaminant. Those criteria are that: i) there is a potential adverse human health effect ; ii) it is known or likely to occur at a level and frequency of concern in Public Water Systems (PWSs); and, iii) regulation presents a meaningful opportunity for health risk reduction.

The EPA has determined that perchlorate presents an adverse human health effect. It is important to note that the EPA has also determined that perchlorate has a greater impact on sensitive populations, specifically pregnant women and developing fetuses.

In evaluating potential exposure, the EPA concluded that perchlorate occurs at levels in excess of its selected health risk level threshold of 15 ug/L in less than 1% of PWSs. Even at this percentage, the EPA reports that its upper end estimate of population exposed to perchlorate at levels in excess of its selected health risk level is 2 million people. If the EPA had applied a more conservative relative source contribution factor, the upper end exposure estimate could be as high as 14 million people. We think that these exposure estimates alone warrant a determination that "regulation presents a meaningful opportunity for risk reduction." However, we are concerned that the EPA's evaluation of impacted public water supply systems (PWSs) may underestimate potential future exposure. By focusing only on known contamination at existing PWSs, the EPA does not consider likely impacts- one of the SDWA criteria. For example, without the strength of a promulgated standard to require cleanup of the impacted aquifers at the PGA North Superfund Site, exposure to perchlorate will likely occur as future PWSs or future entry points to existing PWSs are brought on-line. By considering likely occurrences of perchlorate exposure, we believe that there is a known or likely exposure at a level and frequency of concern.

Response: EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. See response to comment code 6120.

EPA Comment ID: 20935
EPA Comment Code: 5000

Comment: Section 1412(b)(1)(A) of the SDWA provides that the EPA Administrator shall "promulgate a national primary drinking water regulation for a contaminant if the Administrator determines that:

(i) the contaminant may have an adverse effect on the health of persons; (ii)the contaminant is known to occur or there is a substantial likelihood that the contaminant will occur in public water systems with a frequency and at levels of public health concern; and (iii)in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems.

42 U.S.C. [section] 300g-1(b)(1)(A) (Westlaw 2008).

Section 1412(b)(1)(C) of the SDWA further provides that in determining whether to regulate drinking water contaminants, the Administrator must take into consideration:

the effect of such contaminants upon subgroups that comprise a meaningful portion of the general population (such as infants, children, pregnant women, the elderly, individuals with a history of serious illness, or other subpopulations) that are identifiable as being at greater risk of adverse health effects due to exposure to contaminants in drinking water than the general population.

42 U.S.C. [section] 300g-1(b)(1)(C) (Westlaw 2008).

The Environment Department respectfully submits that each of the three criteria in section 1412(b)(1)(A) is met for perchlorate. Moreover, the risk of adverse health effects from perchlorate ingestion is greater for certain sensitive subgroups of the general population as described in section 1412(b)(1)(C).

Comment: Perchlorate Meets the Three Criteria Needed to Justify Promulgation of a National Standard There are three criteria that must be met to justify the promulgation of a national public drinking water regulation:

a) The contaminant may have an adverse effect on human health b) The contaminant occurs with a frequency and at levels of public health concern, and c) The promulgation of standards presents a meaningful opportunity to reduce health risk.

In our view, perchlorate meets all three of these criteria: perchlorate poses a significant health risk, is present at sufficient levels and in a sufficient number of public water systems to constitute a public health concern, and by promulgating a standard, EPA has a meaningful opportunity to reduce health risk.

EPA Comment Code: 5000

Comment: 4. Science-based considerations: The Safe Drinking Water Act (SDWA) has three requirements-all three of which must be met to satisfy the law. The scientific literature addresses these requirements for perchlorate. The science clearly shows EPA's statutory criteria for setting a standard are unmet in this case:

Response: EPA disagrees with the statement that "the science clearly shows EPA's statutory criteria for setting a standard are unmet." In making final regulatory determinations, EPA uses the criteria mandated by the 1996 SDWA Amendments. Specifically, EPA has found that perchlorate may have an adverse effect on the health of persons, that perchlorate occurs or there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern, and that regulation of perchlorate in drinking water systems presents a meaningful opportunity for health risk reduction for persons served by public water systems. The Federal Register notice for this action describes how EPA evaluated these three criteria in light of the best available peer reviewed data to make a preliminary regulatory determination for perchlorate.

EPA Comment Code: 5100 SDWA Criterion #1 – EPA's determination that perchlorate may have adverse effects on the health of persons

EPA Comment Code: 5100

Comment: The Safe Drinking Water Act (SDWA) requires the Administrator to establish an MCL when three conditions are met. The CHPAC feels strongly that all three conditions are met in the case of perchlorate. The first condition, that the contaminant has an adverse effect on the health of persons, is met for perchlorate. Perchlorate interferes with thyroid function and can lower circulating thyroid hormone levels in humans; lowered thyroid hormone levels and consequent impacts on the developing brain have been demonstrated in perchlorate-dosed animals. The developing fetus and infants are vulnerable to perchlorate due to the exquisite sensitivity of brain development to thyroid hormone levels, and the fact that newborns have no stores of this hormone.

Comment: As to the first criterion, it is without dispute that perchlorate in drinking water has anadverse effect on the health of persons. According to the National Research Council, perchlorate can adversely affect the function of the thyroid "because it is an ion that competitively inhibits the transport of iodide into the thyroid" by a protein known as the sodium/iodide symporter.[FN13: NATIONAL RESEARCH COUNCIL, HEALTH IMPLICATIONS OF PERCHLORATE INGESTION 6 (2005).] Iodide deficiency resulting from perchlorate ingestion is more likely to have a negative effect in sensitive populations, such as people with thyroid disorders, pregnant women, fetuses, and infants.[FN14: Id.] In pregnant women, severe iodide deficiency can result in major neurodevelopmental deficits and goiter in their offspring.[FN15: Id.] Lesser degrees of iodide deficiency may also cause important neurodevelopmental deficits in infants and children.[FN16: Id.] EPA expressly recognizes the adverse health effects of perchlorate ingestion.[FN17: See 73 Fed. Reg. 60262, 60275 (Oct. 10, 2008).]

Response: EPA agrees with the commenter. EPA believes the health risk is particularly high for infants and children with high drinking water consumption relative to their body weight.

EPA Comment Code: 5100

Comment: The study by Mendez et.al. [FN13: Mendez, W., Dederick' E., and J. Cohen. 2009. Drinking water contribution to aggregate perchlorate intake of reproductive-age women in the United States estimated by dietary intake simulation and analysis of urinary excretion data. Journal of Exposure Science and Environmental Epidemiology advance online publication 16 September 2009.] further supports findings that the NOEL based RfD is sufficiently conservative and health protective of sensitive subpopulations. This study finds that the total dietary exposure (food and drinking water) of reproductive age women in the U.S. is approximately one-third of the RfD for perchlorate at the 95th percentile, which is complementary to the findings of the joint assessment prepared by EPA-CDC. Given this evidence related to limited exposure potentials and estimated intakes well below the RfD, it is clear that there is limited potential for perchlorate to present a significant adverse affect on the nation's health, including sensitive subpopulations.

Response:

EPA disagrees that there is a limited potential for perchlorate to present a significant adverse effect on the nation's health, including sensitive subpopulations. EPA has determined that perchlorate occurs or there is a substantial likelihood that perchlorate will occur with a frequency and at levels of health concern in public water systems. EPA has made this determination by comparing the best available data on the occurrence of perchlorate in PWSs to potential health reference levels (HRLs) for perchlorate.

Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 μg/L to 47 μg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts.

EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

Comment: a) The SDWA requires that the contaminant must have an adverse effect on the health of persons. The weight-of-evidence, after examining the published scientific literature, demonstrates no documented adverse effects in humans exposed to perchlorate at environmental levels.

Response:

EPA disagrees. EPA disagrees that the "weight of evidence" demonstrates no documented adverse effects in humans exposed to perchlorate at environmental levels. See today's final regulatory

determination for further discussion of the basis of EPA's conclusion that perchlorate may have an adverse health effect on persons.

EPA has determined that perchlorate meets SDWA's criteria for regulating a contaminant —that is, perchlorate may have an adverse effect on the health of persons; perchlorate is known to occur or there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern; and in the sole judgment of the Administrator, regulation of perchlorate in drinking water systems presents a meaningful opportunity for health risk reduction for persons served by public water systems.

After careful review and consideration of public comments on the May 2007, October 2008, and August 2009 notices, and information available at this time, EPA has made this determination by comparing the best available data on the occurrence of perchlorate in PWSs to potential health reference levels (HRLs) for perchlorate as discussed in the regulatory determination final notice.

Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 μg/L to 47 μg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90^{th} percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts.

EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

EPA Comment Code: 5200 SDWA Criterion #2 – EPA's determination that perchlorate occurs infrequently at levels of health concern in public water systems

Response to Code 5200:
EPA has determined that perchlorate occurs or there is a substantial likelihood that perchlorate will occur with a frequency and at levels of health concern in public water systems. EPA has made this determination by comparing the best available data on the occurrence of perchlorate in PWSs to potential health reference levels (HRLs) for perchlorate. EPA collected and analyzed drinking water occurrence data for perchlorate from 3,865 PWSs between 2001 and 2005 under the UCMR 1. The minimum reporting level (MRL) for perchlorate under the UCMR 1 was 4 μg/L. EPA found that 160 (approximately 4.1 percent) of the 3,865 PWSs that sampled and reported had at least 1 analytical detection of perchlorate (in at least 1 sampling point) at levels greater than or equal to the MRL of 4 μg/L. These 160 PWSs are located in 26 States and 2 territories. Of these 160 PWSs, 8 are systems serving 10,000 or fewer people and 152 are systems serving more than 10,000 people. These 160 systems reported 637 detections of perchlorate at levels greater than or equal to 4 μg/L, which is approximately 11.3 percent of the 5,629 samples collected by these 160 PWSs and approximately 1.9 percent of the 34,331 samples collected by all 3,865 PWSs. The average concentration of perchlorate for those samples with positive detections for perchlorate was 9.85 μg/L and the median concentration was 6.40 μg/L.

EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 μg/L to 47 μg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage.

Based on percent of public water system estimates for perchlorate above thresholds of interest in Table 1 in the Federal Register Notice, and the range of potential alternative HRLs, EPA has determined that perchlorate is known to occur or there is a substantial likelihood that it will occur with a frequency and at levels of public health concern.

In light of the discussion in this notice and the information available at this time, the Administrator finds that regulation of perchlorate in drinking water systems presents a meaningful opportunity for health risk reduction for persons served by public water systems. Therefore, EPA will initiate the process of proposing a NPDWR for perchlorate.

Comment: Perchlorate:

Based on state input, it does not appear that perchlorate is being detected in very many public water systems. Thus, while it may be a critical issue at a small number of water systems, it does not appear, at this stage, to be a nationwide problem that impacts most or all states.

Response: See response to comment code 5200.

Comment: The second condition, that the contaminant occurs in public water supplies with a frequency and level of public health concern, is also met for perchlorate. The UCMR data show that millions of Americans are exposed to perchlorate in public supplies at concentrations greater than 6 ug/L, the highest of three recently set state drinking water targets for perchlorate. The only way the second condition is not met is if an inappropriately high health benchmark is set. The CHPAC strongly feels that this is the case with USEPA's HRL of 15 ug/L as this would cause large numbers of infants to receive daily doses of perchlorate that are well above the Agency's RfD.

Response: See response to comment code 5200.

Comment: 10. EPA Underestimates Numbers of At Risk Citizens. Due to the fact that MassDEP believes the HRL should be 2 ppb we conclude more than 16.6 million people are exposed to unsafe levels of perchlorate in their drinking water, and that this is a significant national public health issue.

Response: Regarding your comment that EPA underestimated the number of people at risk, see response to comment code 5200. Regarding your comment that this is a significant national public health issue, EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. This action initiates the process to establish a national primary drinking water regulation for perchlorate including the maximum concentration of perchlorate that is allowed in public drinking water systems.

Commenter Name: Ron Curry
Commenter Organization: New Mexico Environment Department
EPA Document ID: EPA-HQ-OW-2008-0692-1796
EPA Comment ID: 20937
EPA Comment Code: 5200

Comment: As to the second criterion, EPA estimates that 16,000 to 28,000 pregnant women would be exposed to perchlorate at levels exceeding the health reference level (HRL) of 15 "at any given time."[FN18: Id. at 60277.] EPA thus concludes that "perchlorate occurs infrequently at levels of health concern in public water systems."[FN19: Id.] EPA's analysis is seriously flawed for several reasons.

First, the analysis fails to consider future health effects on women who have not yet become pregnant, and on their future fetuses. This failure is at odds with the plain language ofthe SDWA. Section 1412(b)(1)(A)(ii) requires EPA to consider not only whether a contaminant is known presently to occur in public water systems so as to cause public health concern, but also whether "there is a substantial likelihood that the contaminant will occur in public water systems with a frequency and at levels of public health concern."[FN20: 42 U.S.C. [section] 300g-1(b)(1)(A)(ii) (Westlaw 2008) (emphasis added).] Thus, Congress wisely directed EPA to consider potential future health effects in its analysis. But EPA has subtly avoided this consideration in its perchlorate analysis. EPA asks, "Is perchlorate known to occur or is there a substantial likelihood that perchlorate occurs at a frequency and at a level of public health concern in public water systems?"[FN21: 73 Fed. Reg. at 60275 (emphasis added).] EPA then answers this question in the negative because the agency finds that no more than 16,000 to 28,000 pregnant women "could be exposed at levels exceeding the HRL at any given time." EPA effectively takes a snapshot of perchlorate exposure at one instant in time. EPA does not take into account the millions of women who will become pregnant and who could be exposed to perchlorate above the HRL in future months, years, and decades. EPA's failure to account for future health effects is contrary to the SDWA.

Second, the analysis fails to consider health effects on infants. According to the National Research Council, infants comprise a subpopulation that is particularly sensitive to perchlorate exposure. For example, studies have shown that children with a mild iodide deficiency - which perchlorate can cause - have learning disabilities and perform less well on tests of mental and psychomotor ability.[FN22: NATIONAL RESEARCH COUNCIL, supra note 13, at 59.] Moreover, the HRL for infants is likely below the 15 ug/L that EPA determined for pregnant women.[FN23: See letter from Melanie A. Marty, Ph.D., Chair, Children's Health Protection Advisory Committee, to EPA Administrator Stephen L. Johnson, at 2 (Nov. 3, 2008).] EPA's failure to consider the adverse health effects of perchlorate ingestion on infants, a sensitive subgroup, in (preliminarily) determining that perchlorate occurs infrequently in public water systems at levels of health concern is also contrary to the SDWA.

Third, the analysis fails to take into consideration health effects on persons with thyroid disorders. According to the National Research Council, people with thyroid disorders would be expected to be more sensitive to the effects of perchlorate ingestion.[FN24: NATIONAL RESEARCH COUNCIL, supra note 13, at 51.] Again, EPA's failure to consider the adverse health effects of perchlorate ingestion on persons with thyroid disorders in (preliminarily) determining that perchlorate occurs only infrequently in public water systems at levels of public health concern is contrary to the SDWA.

Response: See response to comment code 5200. NRC specifies the fetus of a mother with hypothyroidism or iodine deficiency and low birthweight and premature infants as the most sensitive populations. Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 μg/L to 47 μg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

Commenter Name: Michael Girard
Commenter Organization: Perchlorate Study Group
EPA Document ID: EPA-HQ-OW-2008-0692-2082
EPA Comment ID: 21028
EPA Comment Code: 5200

Comment: 11. Your letter asserts that millions are exposed to perchlorate at levels exceeding the 6 μg/L, the highest of the state MCLs to be established.

In our comments, the PSG has compared the risk opportunity from detects in public water systems (PWSs) between perchlorate and other compounds that EPA has decided not to regulate. The percentage of PWSs with perchlorate detections was very low (3.6 percent) compared to the next lowest unregulated compound, manganese at 68 percent. Sodium, for example, was detected in all PWSs. Perchlorate also has one of the lowest populations served by PWSs with detections above

half the HRL with 2.2 million people. Perchlorate is well within the range of values for the evaluation criterion EPA uses.

Additionally, it bears repeating that EPA has incorporated an additional level of conservatism into an already conservative and health protective NAS-based RfD. Specifically, any exposures above the RfD, if they indeed occur, must first be considered in the context of a non-adverse effect.

Response: Regarding the suggestion to compare the risk opportunity from detects in public water systems between perchlorate and other compounds that EPA has decided not to regulate, EPA does not believe it's appropriate to factor these comparisons into the decision whether to regulate a contaminant. The Administrator will make these determinations on a case-by-case, contaminant specific basis. In making a regulatory determination, the Administrator considers the adverse health effect of the particular contaminant at issue as well as the occurrence or likelihood of occurrence of the contaminant in public water systems with a frequency and at levels of public health concern. In addition, even if such a comparison were appropriate, perchlorate has, at least at the lower levels of public health concern identified, an occurrence that is substantially larger than most of the contaminants for which EPA has made a negative determination. Finally, it is the sole judgment of EPA's Administrator to determine whether there is a meaningful opportunity to reduce health risk for persons served by public water systems.
Regarding the comment that any exposures above the RfD must first be considered in the context of a non-adverse effect, the data underlying the definition of iodide uptake inhibition as a precursor effect and its relationship to the continuum of adverse thyroid outcomes reflects an understanding of effects in adults. The relationship of the precursor event to the adverse outcome in children has not been studied. Thyroid hormone status in neonates and infants is much less resilient than in adults. Generally speaking, they do not have iodide stores sufficient to offset the effects of reduced iodide uptake. Half-lives for circulating hormones are shorter than for adults, making infants and neonates less able to maintain stable hormone levels in the face of a chemical insult. The less resilient infant and neonatal system makes the exposure gap between a precursor event (iodide uptake inhibition due to perchlorate) and an adverse effect (reduced T3/T4 levels) much narrower than for adults. The distinction between the two may be blurred for the very young.

Commenter Name: Michael Girard
Commenter Organization: Perchlorate Study Group
EPA Document ID: EPA-HQ-OW-2008-0692-1855
EPA Comment ID: 21096
EPA Comment Code: 5200

Comment: EPA's UCMR monitoring found a mean concentration of less than 10 ppb in systems with perchlorate - over 100 times lower than the NAS adverse effect level. Only a few systems have found any samples with concentrations greater than 100 ppb. Even the maximum level detected in the US is approximately 50 times lower than the dose at which the NAS panel determined adverse effects could begin. Specifically, the NAS panel noted that "...a sustained exposure of more than 0.4 mg/kg per day would most likely be required to cause a sufficient decline in iodide uptake and thyroid hormone production to result in adverse health effects in normal adults." (NAS 2005) For these reasons, perchlorate is not known or likely to occur in public water systems with a frequency and at levels of public health concern.

Response: See response to comment code 5200.

EPA Comment ID: 28873
EPA Comment Code: 5200

Comment: b) The SDWA requires that the contaminant must be known to occur in PWSs with a frequency and at levels of public health concern. Where perchlorate is found, it is at levels often an order of magnitude below levels that cause IUI, itself a nonadverse effect. EPA data indicate average perchlorate concentrations in public drinking water systems are <10 parts per billion (ppb), and 99% of samples were <7 ppb. These levels are all below the equivalent concentration corresponding to the RfD, assuming a standard EPA default body weight and drinking water consumption rate, as well as the HRL of 15 ppb proposed by EPA in 2008 (U.S. EPA, 2008a).

Response: See response to comment code 5200.

EPA Comment Code: 5210 Derivation of the RSC

Response to Code 5210: EPA routinely applies a relative source contribution (RSC) to allow for the possibility that not all exposure will come from water, recognizing the importance of keeping the total exposure dose (e.g., water plus diet) below the RfD.

EPA believes that use of an RSC for perchlorate is appropriate because the Greer et al. (2002) study, upon which the RfD is based, did not measure the levels of perchlorate in their food, and the sample size is small (37 healthy adults).

The RSC is based on the best available peer reviewed science from the FDA (Total Diet Study) and estimates of exposure based on the NHANES/UCMR data which are robust evaluations of dietary exposure to perchlorate. A more detailed discussion of the derivation of the RSC can be found in the 2009 Federal Register Notice.

Individual Comments

Commenter Organization: American Water Works Association (AWWA)
EPA Document ID: EPA-HQ-OW-2007-0068-0162
EPA Comment ID: 20268
EPA Comment Code: 5210

Comment: In developing a drinking water regulation for perchlorate, EPA needs to address the Relative Source Contribution (RSC) for perchlorate in food and water. The proposal in the May 1st Federal Register notice is a starting point for making an appropriate RSC decision. AWWA recommends that EPA not adjust for RSC, since the subjects in the Greer study were exposed to background levels of perchlorate in addition to an experimental dose, as discussed on pg. 24046 of the May 1st Federal Register notice.

Alternatively, if EPA doesn't accept the above recommendation, then EPA should derive the value of average daily rate of intake from background sources (ADRIB) from the mean (preferred approach) or upper tail (less preferred approach) of the NHANES data specific either to the entire sampled population or to individuals using bottled water. This background value should then be subtracted from the Reference Dose (RfD) and that result used to calculate the Drinking Water Equivalent Level (DWEL). This Modified ADRI approach better approximates the target average daily rate of intake (ADRI) that must be reached to ensure the RfD is not exceeded when water is added to the perchlorate contribution from all other sources combined (ADRIT).

From a technical perspective, some of the options presentation in the May 1st Federal Register simply do not make sense. For example, the EPA option of a regression of the NHANES urinary data versus UCMR is not feasible and should not be considered. It would result in only a couple of dozen data points, an insufficient number to allow a meaningful regression.

Appendix A [See Appendix A in PDF of docket ID EPA-HQ-OW-2007-0068-0162] to these comments is a report by Dr. Douglas Crawford- Brown of the University of North Carolina-Chapel Hill that was prepared on behalf of AWWA. Dr. Crawford- Brown's report explains the above

recommendations in greater detail, comparing and contrasting alternative approaches to selecting a valid RSC value. We ask that his report be considered to be part of these comments.

Comment: BIOMONITORING DATA SUGGESTS THERE IS NO NEED TO ACCOUNT FOR PERCHLORATE EXPOSURES FROM OTHER SOURCES

In the absence of extensive biomonitoring data, EPA has historically created an HRL by multiplying the Drinking Water Equivalent Level (DWEL) of the RfD by a Relative Source Contribution (RSC) for the constituent (a factor of the proportion of exposure expected to come from water). EPA's Support Document outlines several options that EPA suggests for its RSC determination using the biomonitoring data and food surveys. If performed in a scientifically valid manner, the data shows that EPA would calculate an RSC of one (which yields an HRL of 24.5 ppb drinking water equivalent).

EPA also references other approaches to calculate the RSC that appear to be at variance with the best available scientific information, representing overly conservative departures from customary EPA policy or apparently requiring months of additional computations.

Ultimately, it appears that these approaches would yield essentially the same result: an RSC of one, which would render them duplicative.

Attachment 3 [See PDF of docket ID EPA-HQ-OW-2007-0068-0168] provides detailed exploration of the issues raised in this section. Our analysis finds that proper application of the best available science through any of the Agencysuggested approaches will yield the same conclusion - perchlorate in drinking water is a small fraction of total exposure. Using the most reliable of the approaches EPA outlines, the RSC factor is essentially equal to one.

Response: See response to comment code 5210.

Comment: 1.2. The dose-response trial set-up

For clinical dose-response trials similar to the Greer trial, there are 3 possible trial set-ups.

1.2.1. Trial set-up type 1 leading to RSC < 1

The NOEL and therefore the RfD are based on a dose-response trial without food and without drinking water background level contribution.

Or in other words the subjects that are administered the doses have a perchlorate free food diet and drink purified water.

Therefore to arrive at the HRL the food background (FBG) level in the population will have to be estimated and subtracted from the RfD(which is based on the NOEL) . Therefore the RSC < 1 i.e. not all the RfD is attributed to DW.

Example:

Note: The examples are for illustrative purposes only. An UF of 4 is applied to allow smaller figures.

NOEL1= 10ug/kg-day. RfD1 =2.5ug/kg-day

The FBG contains 1.25 ug/kg-day (0.5 or 50% of RfD). Thus the part of the RfD attributed to DW is 0.5 RfD or 50 % of the RfD.

HRL1= maximum level of contaminant that DW should contain = [(RfD1 Ã— BW) /DWI] Ã— RSC=2.5 x70/2x0.5= 43.75 ppb.

Fig.1: NOEL based on dose-response trial without perchlorate food /drinking water background: RSC [see PDF Docket ID EPA-HQ-OW-2008-0692-1798]

1.2.2. Trial set-up type 2 leading to RSC=1

The NOEL and therefore the RfD are based on a dose-response trial with food background (FGB) and without drinking water background (DWBG) level contribution.

Or in other words the subjects that are administered the doses have a food diet with perchlorate background but drink purified water.

Therefore to arrive at the HRL, the FBG level in the population is already included in the NOEL and thus does not have to be estimated and not subtracted from the RfD. Therefore RSC = 1 or 100% i.e. all of the RfD is attributed to DW.

The effective NOEL2 is larger than the dose NOEL1.

Example: NOEL1 = 10ug/kg-day. FBG= 1.25 ug/kg-day. NOEL2 = NOEL1 + FBG=10 + 1.25 = 11.25 ug/kg-day.

RfD2 =1.125 ug/kg-day.

The food diet background as mentioned has already been accounted for.

The part of RfD2 attributed to water is 1 or 100 % of RfD2.

HRL2 = [(RfD2Ã— BW) /DWI] Ã— RSC=1.125 x70/2x1 = 39.4 ppb.

Or in other words, since NOEL1 is a dose added on top of the food background (see fig. 2) the whole RfD is attributed to DW.

Fig. 2: NOEL based on dose-response trial with perchlorate food background and without drinking water background: RSC = 1 [see PDF Docket ID EPA-HQ- OW-2008-0692-1798]

1.2.3. Trial set-up type 3: RSC is arithmetically >1

The NOEL and therefore the RfD are based on a dose-response trial with food background and with drinking water background level contribution.

Or in other words the subjects that are administered the doses have a food diet with perchlorate background and drink already contaminated water.

Since the NOEL1 is added on top of the food background (see drawing), the whole RfD is attributed to DW.

Now, the DW background (DWBG) itself is on top of the NOEL1 .Therefore, arithmetically, the RSC must be <1.

Example 1: NOEL1 = 10ug/kg-day. FBG= 1.25 ug/kg-day. DWBG = 0.625 ug/kg-day. NOEL3= NOEL1 + FBG +DWBG=10 + 1.25 +0.625 = 11.9 ug/kg-day. RfD3 =1.19 ug/kg-day.

HRL3 = [(RfD2 +DWBG) Ã— BW)/DWI] Ã— RSC= [(RfD3 Ã— BW)/DWI] Ã— RSC= (1.19 x70/2) x1 = 41.65 ppb.

Example 2: Assume perchlorate 1.5 ppb DW background and NOEL2 =0.7 ug/kg-day.

1.5 ppb background DW= 1.5 /70 x2= 0.04 ug/kg-day and HRL3 = (0.7+0.04) x 70 /2 x1 =26 ppb which arithmetically comes down to an RSC of 1.04 as 0.74x70/2 x 1.04= 26 ppb as well.

Fig. 3: NOEL based on dose-response trial with perchlorate food background and with drinking water background: RSC > 1 [see PDF Docket ID EPA-HQ- OW-2008-0692-1798]

More considerations about the RSC and practical examples can be found in: http://oehha.ca.gov/water/reports/howdsot.html.

Comment: 3.1. RSC check

If the contribution from food would be 10% (see EPAâ€™s table 8) and which is derived from the TDS study model then of the 0.04 ug /kg-day total average perchlorate background exposure, 0.036 ug /kg-day would come from water.

Even, as already noted above, this is low compared to the other goitrogens, it would still translate into a US average drinking water content of 1.3 ppb (0.036 x70/2) which appears somewhat high but still close to EPAâ€™s data on U.S. wide DW perchlorate levels. Therefore the TDS model may be an accurate enough tool to estimate RSCs.

Response: See response to comment code 5120 for a discussion of the relative source contribution.

Comment: EPA's Calculation of the Relative Source Contribution for its Preliminary Determination also Reveals that the Food Contribution is Below the Level of Concern.

The US Centers for Disease Control's National Health and Nutrition Examination Survey (NHANES) biomonitoring data provides a superior measure of actual human exposure to perchlorate from all sources, including food and water. FDA's TDS and food sampling data, which provides an approximation of human exposure to perchlorate from food, in fact validates EPA's calculation of the relative source contribution from food.

Comment: Relative Source Contribution (RSC) MDH acknowledges the extensive national database of perchlorate exposure information that includes perchlorate concentrations found in food and beverages as well as biomonitoring data. We understand EPA's use of the NHANES biomonitoring data to estimate the 90th percentile food dose for pregnant women leading to the derivation of the drinking water RSC. For infants and young children, EPA states that the RSC is based on the central tendency dietary perchlorate exposure derived from FDA's Total Diet Study. MDH does wonder whether an RSC based on average dietary perchlorate exposure will protect individuals who have higher dietary doses. However, EPA's RSC for children 12- months and younger (0.59) based on the central tendency exposure is not much higher than the default RSC used by MDH for infants (0.5).

MDH uses 0.2 as the relative source contribution (RSC) default value for volatile chemicals for all exposure durations. However, for non-volatile chemicals, an RSC of 0.5 is used for acute and short-term exposure durations and 0.2 is used for subchronic and chronic exposure durations.

Response: See response to comment code 5210. EPA believes that the central or mean estimates of dietary intake of perchlorate from the total diet study are the best available peer reviewed data for determining the relative source contribution.

Comment: 2) Exposure from other sources

The best evidence to date suggests that perchlorate is ubiquitous in the United States but UCMR data and other research suggest that little of this exposure is via drinking water. In addition, USEPA used the Greer et al study that used individuals who did not control or measure their exposure to perchlorate from food, a major source of perchlorate. This means that the ubiquitous background of perchlorate exposure found in the United States was built into the study, which was measuring the

effect of additional exposure above the background. This, along with the use of the no observed effect level (NOEL) versus no observed adverse effect level (NOAEL), actually makes the study more robust and has additional protection built into it. When the USEPA later uses uncertainty factors in their review, they are double-counting those factors.

The use of a relative source contribution (RSC) does not appear to be warranted in this situation. Given the very small contribution to perchlorate exposure from drinking water, the precedent set by USEPA when they evaluated sodium was that the RSC should be ignored. It is also important to note that other more dominant goitrogens have much greater occurrence than perchlorate in drinking water.

Response: See response to comment code 5210 for a discussion of the RSC.

EPA does not believe the conditions for the sodium regulatory determination are comparable to those for perchlorate. Dietary exposure alone does not exceed the reference dose; however, for some people in water systems with perchlorate contamination the dietary exposure combined with drinking water exposure may result in a total dose that exceeds the RfD for perchlorate. This is of particular concern among sensitive life stages.

EPA Comment Code: 5210

Comment: Furthermore, based upon available epidemiological and other human studies, the use of RSC is inappropriate. For these reasons, it is unlikely that modeling a compound known to form naturally and occur ubiquitously represents an appropriate representation of actual conditions.

Response: See response to comment code 5210.

EPA Comment Code: 5220 Derivation of the HRL

Response to Code 5220: EPA has reversed its October 2008 preliminary determination not to develop an NPDWR for perchlorate and now concludes, based on the analysis presented in today's notice, that perchlorate meets the criteria for regulating a contaminant in Section 1412(b)(1)(A) of SDWA. EPA has found that 1.) perchlorate may have an adverse effect on the health of persons; 2) perchlorate is known to occur or there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern; and 3) in the sole judgment of the Administrator, regulation of perchlorate in drinking water systems presents a meaningful opportunity for health risk reduction for persons served by public water systems. In proposing a national primary drinking water standard, EPA will seek public comments on the proposed standard, and analyses on which it is based, pursuant to SDWA requirements.

EPA has made this determination by comparing the best available data on the occurrence of perchlorate in PWSs to potential health reference levels (HRLs) for perchlorate. HRLs are not final determinations about the level of a contaminant in drinking water that is necessary to protect any particular population. Rather they are benchmarks against which EPA compares the concentration of a contaminant found in public water systems to determine if it is at levels of public health concern.

In the October 2008 preliminary regulatory determination, EPA had derived a single HRL of 15 µg/L based upon the RfD, an estimate of perchlorate exposure from food for pregnant women, and traditional adult body weight (70 kg) and drinking water consumption (2 L/day) values. This single HRL was derived to reflect exposure to a pregnant woman and her fetus, which the NRC identified as "the most sensitive population."

Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts.

EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination. EPA has compared these values to the data provided by PWSs subject to the first Unregulated Contaminant Monitoring Rule (UCMR 1). EPA collected and analyzed drinking water occurrence data for perchlorate from 3,865 PWSs between 2001 and 2005 under the UCMR 1. The minimum reporting level (MRL) for perchlorate under the UCMR 1 was 4 µg/L.

EPA found that 160 (approximately 4.1 percent) of the 3,865 PWSs that sampled and reported had at least 1 analytical detection of perchlorate (in at least 1 sampling point) at levels greater than or equal to the MRL of 4 µg/L. Table 1 of today's notice presents the number and percentage of PWSs

that reported perchlorate at levels exceeding various threshold concentrations. Note that the MRL for perchlorate under the UCMR 1 was 4 μg/L.

Given the range of potential alternative HRLs, EPA has reversed its October 2008 preliminary determination not to regulate perchlorate in drinking water. Based on the data in Table 1 and the range of potential alternative HRLs, EPA has determined that perchlorate is known to occur or there is a substantial likelihood that it will occur with a frequency and at levels of public health concern.

Table 2 of today's notice presents EPA's estimates of the population served by PWSs that were monitored under UCMR 1 for which the highest reported perchlorate concentration was greater than the thresholds identified in Table 1. These population estimates are for people at all life stages. EPA has determined that a NPDWR for perchlorate could reduce perchlorate exposures for these populations to levels below the potential alternative HRLs that EPA has identified as levels of public health concerns for purposes of this determination, and that such exposure reductions present a meaningful opportunity for the reduction of health risks for persons served by PWSs.

Comment: REVIEW OF THE NAS REPORT AND SUBSEQUENT PEER-REVIEWED STUDIES AFFIRMS USE OF THE RfD AS THE HEALTH REFERENCE LEVEL

EPA must often make important decisions on the basis of less information than it would wish; and perchlorate is a welcome exception.

There is extensive scientific literature, most notably a comprehensive, authoritative review of the range of peer-reviewed studies by the National Research Council of the National Academy of Sciences (NAS). The success of EPA, along with other agencies, in obtaining this review has put the Agency in an unusually well-informed position, backed by the deliberations and judgment of the nation's highest scientific body. The NAS Report, followed by the Agency's own RfD process, is supplemented by subsequent, peer-reviewed studies. Taken together, these comprise a solid basis for an EPA regulatory determination.

EPA's RfD is the best health benchmark to use as the health reference level (HRL). EPA concurred with the conclusion of the NAS panel in the adoption of the panel's recommendation as EPA's RfD. This RfD is based on the NAS panel's emphatically conservative approach of establishing the point of departure at the No Observed Effect Level (NOEL), rather than EPA's customary No Observed Adverse Effect Level (NOAEL). Consistent with EPA's design for RfDs, the NAS panel selected its recommended RfD to be protective of all sensitive populations. Subsequent peer-reviewed studies affirm and reinforce the conclusion that the RfD is a conservative, health protective value that protects all members of society, even the most sensitive population.

Further discussion of these studies and our comments is contained in Attachment 1 [See PDF of docket ID EPA-HQ-OW-2007-0068-0168].

Response: EPA is utilizing the RfD to derive potential alternative health reference levels and evaluate the opportunity for health risk reduction through a drinking water regulation for perchlorate. See response to comment code 5220.

EPA Comment Code: 5220

Comment: 2. EPA's HRL Is Not Sufficiently Health Protective. MassDEP continues to believe that EPA's Reference Dose (RfD) and the associated Health Reference evel (HRL) for drinking water for perchlorate are insufficiently health protective of neonatal exposures. There is compelling evidence to support a national drinking water standard for perchlorate at a value well below EPA's HRL of 15 ppb.

* Literature publications (Zoeller and Rice, 2004; Zoeller, 2006; Ginsberg et al., 2007) and state agency risk assessments (MassDEP, 2006; CA, 2004) support a more health protective RfD and drinking water value. EPA's HRL of 15 ppb is 7.5 times higher than MassDEP's drinking water standard of 2 ppb and 2.5 times higher than California's standard of 6 ppb. EPA's evaluation includes no discussion of these alternative assessments. * The results of Blount et al (2006) and Steinmaus et al (2007) demonstrate thyroid effects associated with a dose of 0.06 ug/kg/day in iodide insufficient women, which is well below, and calls into question the protectiveness of, EPA's RfD of 0.7 ug/kg/day. * Although acknowledged in EPA's evaluation, potential interactive effects between thiocyanate, a metabolite of cyanide found in tobacco smoke and some common foods, and perchlorate, were not accounted for. Such interactions heighten concern regarding perchlorate induced thyroid hormone effects in women with serum iodine levels < 100 ug/L. * Use of a more appropriate and health protective RfD would lower the acceptable drinking water limit for perchlorate, resulting in a substantial increase in the total number of citizens exposed to unacceptably high levels of this toxicant from drinking water. This would clearly create a "meaningful opportunity for health risk reduction" through a national perchlorate drinking water regulation under the Safe Water Drinking Act.

Response: See response to comment code 5220.

Comment: 3. Infant Exposures at the HRL Exceed EPA's Insufficiently Protective RfD. EPA's calculations (Table 8, Federal Register publication) demonstrate that perchlorate intake by nursing and bottle-fed infants and children to 2 years of age, attributable to the consumption of drinking water at 15 ug/L (and not even considering other dietary sources of exposure) would substantially exceed EPA's insufficiently health protective RfD value. Based on EPA's own calculations, a bottle-fed infant would receive a dose of perchlorate 5 times higher than EPA's RfD and 50 times higher than MassDEP's RfD. Consistent with EPA's assessment, in a study conducted in Texas Dasgupta et al. (2008) also showed that the majority the infants (9 out 13 infants) in their study ingested perchlorate at a level that exceeds the EPA reference dose. Furthermore, this study indicates that breast milk iodide concentrations decrease as perchlorate levels increase in breast milk (Dasgupta et al., 2008), potentially raising risks to nursing infants. Due to potential impacts on children's health, this data alone justifies the establishment of a lower, more appropriately health protective HRL for perchlorate. By discounting this information in the evaluation, EPA is de facto adopting an even

higher, less protective RfD for these sensitive subgroups. EPA's explanation for discounting these findings- that the model's predicted iodide uptake inhibition (IUI) level at 15 ppb would be insignificant- is unjustified for at least three reasons.

a. The predicted IUI in these groups is very uncertain due to model limitations.

b. Although EPA indicates that iodide uptake inhibition of 2.2% is non- adverse, no objective data exists to support this determination and no objective safe level of IUI, especially in the neonate, has been established. In fact, the Blount et al. (2006) and Steinamus et al. (2007) studies indicate that 2.6 ug/L of urinary perchlorate (which equates to an approximate dose level of 0.06 ug/kg/d in iodine deficient women was associated with decreased T4 and increased TSH levels, consistent with the mode of action of perchlorate. Iodide uptake inhibition at this dose level would be predicted by the model to be very small suggesting either that the model is inaccurate; the effect is not solely due to IUI or low levels of IUI are adverse.

c. Allowing up to 2.2% iodine uptake inhibition also exceeds NRC's hypothesized non-adverse effect level of 1.8% IUI (NRC, 2005) although 1.8% IUI is considered an adverse effect level by many scientists (US EPA 2002; Ginsberg and Rice, 2005; and MassDEP, 2006).

Response: See response to comment code 5220 for a discussion of the alternative Health Reference Levels. Regarding the predictions of iodide uptake inhibition Physiologically-Based Pharmacokinetic (PBPK) Modeling , EPA reviewed, modified, and applied the perchlorate PBPK models, which were originally developed by Merrill et al. (2005) for adults and Clewell et al. (2007) for other life stages, to estimate the iodide uptake inhibition in the thyroid for each life-stage (73 FR 60262; USEPA 2008a). Estimated ingestion rates were then used to estimate the internal dose and resulting iodide uptake inhibition for several life stages, including susceptible populations (e.g., pregnant women and their fetuses, as well as breast-fed and bottle-fed infants).

In the August 2009 notice, EPA stated that it was re-evaluating how best to incorporate the PBPK modeling analysis into its evaluation of perchlorate- if at all. The Agency sought comments on ways to use the PBPK modeling analysis to inform the regulatory determination.

Several commenters support the use of the PBPK model to inform the regulatory determination only if the significant limitations of the current model are addressed. For example, the inability of the model to reflect iodide nutritional status was cited by commenters and three of the four peer reviewers as an important limitation. Also, several commenters stated that the risks to breast-fed infants and young children are not adequately addressed. They challenged that the modeling analysis is based on average weight infants and healthy adults, while the sensitive life stages for perchlorate include premature infants and hypothyroid women.

After further consideration of the peer review and public comments, EPA concludes that the PBPK modeling analysis, in the context of the perchlorate regulatory determination, is useful in examining which life stages are most susceptible to the effects of perchlorate. For example, the model indicates that a fetus may be seven times more sensitive to the effects of perchlorate than a pregnant woman. The model also allows for the estimation of the concentration of perchlorate in breast milk (thus breast-fed infant exposure) at various maternal perchlorate exposure levels. However, because of the stated limitations, EPA has decided the model does not directly bear on the current decision

regarding the need for a NPDWR for perchlorate. EPA is continuing to evaluate whether the model could be used in setting a NPDWR for perchlorate.

Commenter Name: Jeanne Herb

EPA Comment Code: 5220

Comment: Further, it is our opinion that the information provided in the proposal indicates that 15 ug/L is not a health protective drinking water concentration, and that the HRL should be set at a lower level that is protective of public health for all exposed subpopulations. A primary concern is that the exposure and health risks of bottle-fed infants, as predicted by the PBPK model, are ignored in the proposal. The PBPK model predicts that when the perchlorate concentration in water used to prepare formula is 15 ug/L, 7-day and 60-day old bottle-fed infants are exposed to more than 5 times the RfD, and that iodide uptake in 7-day old infants is decreased by 2.2% (Table 8). Even if the model were to use the median rather than the 90th percentile water intake, the RfD would be greatly exceeded. The model also predicts that a breast-fed infant would be exposed to more than twice the RfD from perchlorate in the mother's milk due to maternal ingestion of water contaminated with 15 ug/L perchlorate. The weaned 6-12 month old is predicted to be exposed to almost 3 times the RfD when water with 15 ug/L perchlorate is used to prepare fluids and foods.

Comment: Decision not to regulate perchlorate based on population exposed above the HRL

The estimation of the number of people exposed to perchlorate at a level of public health concern in public drinking water is determined by the perchlorate concentration chosen as the HRL. Setting an HRL at an inappropriately high concentration, 15 ug/L, greatly reduces the size of the population predicted to be exposed at a level of public health concern. Table 2 of the proposal shows that approximately 2 million people (in 0.8% of systems) or, alternatively, an estimated 0.9 million people served by 0.29% of points-of-entry (POEs) are exposed at or above an HRL of 15 ug/L. USEPA states that this number of people is not sufficient to warrant regulation. However, if the level were to be set at 5 ug/L, for example (a concentration that still would result in bottle-fed infants being exposed slightly above the Reference Dose, based on the exposure assumptions in Table 8), 5 to 7 times more individuals would be exposed above the HRL than at 15 ug/L: 14.6 million people (3.2% of systems) or 4 million people served by 1.9% of POEs would be exposed above 5 ug/L. Therefore, by setting the drinking water concentration higher than it should be from a health viewpoint, USEPA has also significantly minimized the need for regulation of perchlorate from an occurrence viewpoint.

Comment: * Roughly, 17% of reproductive-aged women in the United States are especially susceptible to perchlorate toxicity due to inadequate dietary intake of iodine and are susceptible to hypothyroxinemia and hypothyroisism during pregnancy. There is a possibility that some women in the child-bearing age in the United States are getting less than the recommended daily iodide intake level.

* Iodine deficiency during early pregnancy may cause irreversible neurodevelopmental deficits in offspring.

* Exposure to perchlorate is likely to further reduce iodide uptake by the thyroid.

* As many as 350,000 pregnant women within the United States may be exposed at any given time to perchlorate levels considered unsafe.

Because there is uncertainty regarding our understanding of perchlorate toxicity, exposure, and presence in the environment, a cautious approach for protecting sensitive populations should be taken. The department concludes that EPA's health reference level is not adequately protective of the health of sensitive subpopulations and the determination that a meaningful opportunity for risk reduction through the regulation of perchlorate in drinking water is not supported from a public health perspective.

Comment: Many experts disagree with your assessment that drinking water with 15 parts per billion of perchlorate is safe and acceptable. Scientists from the California Environmental Protection Agency and the Massachusetts Department of Environmental Protection have set stricter standards to will ensure that the most vulnerable populations -- pregnant women, infants, and small children -- are protected from the adverse impacts of perchlorate.

EPA's analysis fails to consider that the combination of food and drinking water exposure to perchlorate in the U.S. population exceeds the reference dose set by EPA. Nor does it incorporate the more protective methodology behind the recent state regulatory actions. These flaws must be

remedied for the sake of the millions of U.S. families exposed to dangerous levels of perchlorate contamination.

Thank you and God Bless.

Comment: Dear US EPA,

As a community water system in the State of California, Anaheim Public Utilities believes that continuing the process for establishing a drinking water standard for perchlorate would fall well within SDWA guidelines. Although the Preliminary Regulatory Determination on Perchlorate finds that a health reference level of 15 ug/l appears to be a reasonable estimate for a potential drinking water standard, the States of California and Massachusetts have established drinking water standards for perchlorate at much lower levels. Therefore, we conclude that there is ample evidence that the actual level of public health concern for perchlorate is truly much lower than the health reference level mentioned in the Preliminary Regulatory Determination.

Thank you for your consideration of this comment. Sincerely,

Dick Wilson Environmental Services Manager Anaheim Public Utilities Department 714-765-4277 dwilson@anaheim.net

Comment: IV (B), p 60275. The formula used to calculate the health risk level for perchlorate uses the default body weight for an adult male, and default drinking water consumption of 2 L/day. Recent EPA exposure assessment guidance (U.S. EPA, 2004) recommends using exposure data more relevant to the actual persons at risk. OEHHA has accepted that guidance in its risk assessments and is disappointed that EPA itself has not. Specifically, since the greatest risk of exposure to perchlorate appears to be in pregnant women and in infants, we believe that body weights and drinking water consumption values which are fully protective of these groups should be utilized in this risk assessment. The upper 95th percentile drinking water consumption rates appear to us to be adequately protective. Applying this health-protective value to the EPA reference dose of 0.7 ug/kg-day and relative source contribution of 0.62 yields the following:

Pregnant women: (0.0007 mg/kg-day x 0.62) / 0.055 L/kg-day = 0.008 mg/L

For infants, the comparable calculation is more complicated, because the reference dose of 0.7 ug/kg-day was calculated for an adult, as was the relative source contribution. However, if those values were retained, the following result is obtained:

Infants: (0.0007 mg/kg-day x 0.62) / 0.221 L/kg-day = 0.002 mg/L

If the starting point for calculation of the RfD were the BMDL of 0.0037 mg/kg- day, these numbers would be correspondingly lower, although again, a health- protective dose and relative source contribution for infants should be calculated separately. It seems to us that numbers in this range should be being used in making the decision whether or not to regulate perchlorate in drinking water.

IV (B)(3), p 60277. Table 7, Health Reference Levels for Pregnant Women. We are concerned that EPA continues to use the obsolete default values of 70 kg for body weight and 2 L/day of water consumption when these values certainly do not apply to pregnant women. These defaults are specifically intended for the population in general, and should be superseded by more specific and appropriate values when a risk assessment is being conducted for a defined subpopulation (U.S. EPA, 2004, 2005).

Comment: EPA's flawed assessment still finds that millions of people are exposed to potentially harmful levels of perchlorate: EPA's assessment is fundamentally flawed for the reasons described above. In this assessment, EPA determines that 15 ug/L (15 ppb) is an appropriate health reference level (HRL); this number was arrived at, in part, by using data from the unpublished study that was just described in the preceding section of this document. It should be noted that in the Blount study, women with lower iodine levels who had exposure to perchlorate in drinking water as low as 2 ppb had an associated 11% decrease in thyroid hormone levels (Blount et al. 2006b). It is clear that the EPA HRL is not protective of public health since levels of perchlorate exposure far below 15 ug/L result in significant changes in thyroid hormone levels.

Response: See response to comment code 5220.

Comment: EPA concludes that a health risk level (HRL) of 15 ug/L would be adequate to protect public health. We strongly disagree. As documented in the previous sections, the HRL is based on a flawed reference dose, and does not adequately take into account either the role of individual variability or iodine status factors that recent studies have demonstrated play a critical role in determining an individual's response to perchlorate. When combined with what is known about the biology of thyroid homeostasis and the increased sensitivity of the fetus and neonate, it is clear that the HRL will not adequately protect sensitive subpopulations in the US.

Comment: Determining the number of facilities where perchlorate concentrations exceed a health-protective level depends on the selection of a health-protective level; as a result of this circular logic, if the health risk level is under- protective, then a smaller number of facilities will be identified. A lower, more protective health risk level will identify a larger number of facilities, and therefore exposed individual. As we have documented in the previous sections, the health risk level selected by EPA is not adequate to protect sensitive subpopulations. Hence, EPA underestimates the number of facilities that are supplying perchlorate-contaminated drinking water.

Comment: Summary

1. When to apply a RSC and when not

Applying a RSC when determining the HRL for perchlorate is not justified as the NOEL found thru the clinical dose-response trial on which the HRL is based already incorporates a RSC thru the background level that was present.

Response: See response to comment code 5210.

EPA Comment Code: 5220

Comment: -Consequently, to be health protective, a joint DW HRL of nitrate and perchlorate of 45 ppb total perchlorate equivalent should be proposed.

-If for nitrate the same UF=10 would be applied as for perchlorate, the HRL for perchlorate alone, after subtraction of this adjusted nitrate MCL would be 26.7 ppb which is close to the 27 ppb derived from the total perchlorate equivalent RfD when attributing a 40% share of nitrate plus thiocyanate in this goitrogenic background conform with the NHANES data. It is also close to the current EPA DWEL of 24.5 ppb.

Consequently those 2 alternative data based approaches seem to confirm once more the NRS RfD and the current EPA DWEL based on a RSC of 1.

Response: While EPA acknowledges that nitrate and thiocyanate have the same mode of action as perchlorate, and that the effects of combined exposure to perchlorate, nitrate, and thiocyanate are additive, EPA does not believe there are sufficient scientific data currently available to assess and characterize the combined risk of these contaminants. EPA has committed to a drinking water strategy that outlines four principles to expand public health protection for drinking water (USEPA, 2010b). One of these principles is to address contaminants as groups. However, EPA does not believe that regulatory action to address perchlorate should be further delayed. Therefore, EPA is developing a proposed rule for perchlorate. Once the perchlorate standard is promulgated, EPA is required to review and revise, as appropriate, its drinking water standards at least every six years. Any revision must at least maintain or improve public health protection. When there are sufficient scientific data to assess the cumulative risks of perchlorate and other contaminants, EPA will review this information to evaluate whether any revisions of NPDWRs are appropriate.

Comment: -Also the PBPK model used by EPA arrives at a HRL that closely matches the one obtained by using the total perchlorate equivalent level and applying an RSC =1.

Because food exposure data and other relevant variables were recently available including for the most sensitive subpopulations, EPA chose to use a refined approach rather than EPAâ€™s former "default" approach to estimate the RSC leading to the HRL. However it may be useful to compare this HRL and the HRL that would have been obtained by using the former "default" RSC approach particularly when adding additional considerations and evidence not taken into account neither by the former not by the latter approach.

Response: See response to comment code 5220 for a description of the potential alternative HRLs and comment code 5210 for a discussion of the RSC.

Comment: 1. Determination of HRL applying an RSC or not

1.1. Introduction

(Note: from hereon we specify the NOEL, RfD and HRL as NOEL1,NOEL2 ,NOEL3 and NOEL4 ;RfD1,RfD2 ,RfD3 and RfD4 ;HRL1 , HRL2, HRL3 and HRL4 according to their subsequent specific meanings in this comment while with NOEL, RfD and HRL is meant their general meaning).

EPA bases its HRL for DW (drinking water) on the NRC (National Research Council) RfD (Reference Dose, 0.7ug/kg-day) according to the following equation:

HRL = [(RfD Ã— BW)/DWI] Ã— RSC with BW= Body weight = 70 kg and DWI = drinking water daily intake in litres.

Response: No response necessary to this summary of EPA information.

Comment: 2. The very particular case of perchlorate

Two particular considerations should be taken into account in determining a "state of the art" HRL for perchlorate besides the fact that the RSC should be equal to 1 and the fact that the full effective NOEL and RfD should be taken into account.

A. The background is known for perchlorate

To our knowledge this is the first time that background data are available that would allow to calculate an effective NO(A)EL for a contaminant for which a RSC is not needed to set a HRL.

Using the data and regression curves presented in Blount et al., (2006,b) (2) the average urinary perchlorate level of 2.84 ug/l (with a 95% confidence interval of 2.54-3.18 ug/l) translates into an average exposure or total background(food +DW) of around 0.04 ug /kg-day (which is 17times lower than the 0.7 ug /kg-day RfD).

The estimation of the effective Greer NOEL (NOEL3) is therefore still ? NOEL1 ? Âµg /kg-day. At first sight this is reassuring as it does not matter much if the background perchlorate would be

taken into account or not or whether the background food perchlorate level would have been subtracted already or not since NOEL3 is almost equal to NOEL1 meaning that also HRL3 would be almost identical to the HRL1 of 24.5 ppb.

It also shows that perchlorate background levels (food +DW) in the U.S. population are very low to start with as they represent only around 0.5 %(= 0.04/7) of the effective perchlorate NOEL3 and apparent perchlorate NOEL1 and 5% of the RfD.

Yet there is more to be considered.

Response: See response to comment code 5210 for a discussion of the RSC and comment code 5220 for a discussion of the potential alternative HRLs.

Commenter Name: Herwig Opdebeeck

EPA Document ID: EPA-HQ-OW-2008-0692-1798
EPA Comment ID: 20969
EPA Comment Code: 5220

Comment: Yet, surprisingly, even though EPA refers to those goitrogens when discussing the Blount et al., (2006b) (2) biomonitoring study it does not take into account the available data that would allow it to significantly refine the RfD and the corresponding HRL.

If EPA would have done so, EPA would have found that the background level of the other goitrogens are, as noted, much more important than the one of perchlorate itself and should therefore been taken into consideration a priory. As mentioned the total perchlorate equivalent RfD should have been 1.28 ug/kg-day and the old DWEL of 24.5 ppb should be replaced by one of around 45 ppb for [perchlorate +nitrate /240].

The current MCL for nitrate is 44 ppm (10 ppm as nitrate) which translates into a 183 ppb perchlorate equivalent (44,000/240).

For Methemoglobinemia on which the nitrate MCL was based, a RSC of 1 and a UF of 1 was applied. A RSC of 1 was justified as explained above however an UF of 1 may, as suggested by CDC (9), or may not have been justified .However for nitrate to be as health protective for iodine uptake inhibition as the perchlorate RfD the same UF as perchlorate should have been applied when assuming that 44 ppm is a NOEL. On the contrary most probably 44 ppm is already above the NOEL (10).

In that case the new nitrate MCL would have an equivalent of 18.3 ppb perchlorate. This would then leave a HRL of 45 -18.3 = 26.7 ppb for perchlorate alone which, by the way, is close to the current EPA DWEL of 24.5 ppb.

Response: See response to comment ID 20958 under comment code 5220.

Commenter Name: Herwig Opdebeeck

EPA Comment ID: 20971
EPA Comment Code: 5220

Comment: 3. A few checks of the current EPA approach in setting a HRL

As noted before, when, because of the trial set-up, the dose that allowed to determine a NOEL (or NOAEL) was not complementary to a background dietary level, the application of an RSC< 1 is necessary to come to a HRL for water only.

In that case most of the time a default RSC is used because of lack of more precise data. This makes the RSC an imprecise tool .Therefore a data based estimate such as the FDA TDS model used by FDA would, while still a model, have been an improvement.

However, as explained, trying to derive a HRL from the perchlorate RfD, applying an RSC<1 is not justified since the food contribution was already taken care of.

Yet the data on the perchlorate background and the total equivalent perchlorate background can be used to check the RSC based on the FDA TDS model and to check the EPA HRL based on the PBPK model

Response: See response to comment code 5210.

Comment: 3.2. HRL check

For the most sensitive population, as designated by EPA, and assuming a same nitrate and thiocyanate background intake as the Greer cohort , the perchlorate food dose for the highest 10% of this population segment is 0.26 ug/kg-day(see EPA table 6).

The (new) RfD that remains for DW would then be: 0.77-0.26 = 0.51 ug/kg-day which leads to a DW HRL of 17.8 ppb (0.51x70/2) which is close to the 15 ppb found by EPA for this sensitive group.

EPA Comment ID: 20985
EPA Comment Code: 5220

Comment: In simple terms, the HRL is the maximum contamination level of perchlorate that could be in drinking water, and still keep daily human consumption levels from exceeding the RfD of 0.7 ug/kg/day. EPA reports that for pregnant women, exposure to perchlorate from food is 0.263 ug/kg/day at the 90th percentile (based on data from a national food survey), representing nearly 38% of the RfD, thus leaving an RSC (Relative Source Contribution) for water of 62% (FR at 60276). This is equivalent to 0.437 ug/kg/day from water, assuming an average body weight of 70 kg, and a daily water consumption of 2 L (90th percentile adult water consumption). That is, 0.437 ug x 70 kg body wt. = 30.6 ug perchlorate in 2 L (the daily consumption amount). This is 15 ug/L, or 15 ppb, the HRL.

Response: No response is necessary to the information provided by the commenter.

Comment: The EPA has determined that setting a NPDWR will not present a meaningful opportunity for health risk reduction based on assessments done by multiple authoritative scientific bodies, numerous well conducted human and animal experiments using a range of doses of perchlorate, and the occurrence and concentration of perchlorate in drinking water systems in the U.S. One of the rationales for this decision was the calculation of the HRL which was based on the RfD. The RfD combined this previous knowledge to determine a dose which is well above the threshold in healthy adults that does not cause inhibition of iodide uptake and dividing that dose by 10 to account for sensitive populations.

Comment: III. IODINE SUFFICIENCY IN THE UNITED STATES

A significant degree of attention and concern related to perchlorate exposure has been focused upon the hypothetical iodine-deficient person. However, unless the doses of perchlorate are sufficient to significantly impair long term (not transient) iodide uptake, which would be considerably greater than 0.007 mg/kg-d (~240 ppb based on healthy adults; Greer et al. 2002), perchlorate exposure would not exacerbate iodine deficiency. As stated above, this dose was adjusted by an uncertainty ("safety") factor of 10. Thus, the approach used by EPA in deriving their HRL based on the RfD of 0.7 ug/kg-d, remains a conservative and health protective approach that accounts for substantial uncertainty. The NRC definitively states

"...a dose that does not inhibit thyroid iodide uptake will not affect thyroid function, even in subjects with an abnormal thyroid gland or a very low iodide intake."

There is concern that there are low iodine levels in the U.S. population. The concern is that low iodine levels in a pregnant woman for prolonged periods of time can cause a change in thyroid hormones that may affect the neurodevelopment of the fetus.

First and foremost, it is important to note that no study has demonstrated that exposure to environmentally-relevant levels of perchlorate causes or is associated with iodine deficiency. Taken at face value, Blount et al. (2006) show an association between thyroid disruptions and perchlorate; however, even if this association represented an actual biological effect at doses below the inhibition of iodine uptake, this hypothetical effect does not raise or lower the measured thyroid hormones outside of the normal ranges and do not show any adverse effect due to the exposure. An epidemiological study of chronically exposed populations in Chile, including children who were exposed throughout gestation via maternal exposure and in infancy through breastmilk and later dairy, show no adverse effects with exposure much higher than the RfD even with iodine intakes similar to that in the U.S. (Tellez et al., 2005).

Second, the TDS and NHANES both show that population intake of iodide exceed the recommended adequate intake for iodine (Murray et al., 2008; Blount et al., 2006). Although there have been questions regarding iodine sufficiency in the U.S., Borak (2005) points out that there has not been consistency regarding the application of WHO definitions of iodine insufficiency and interpreting the great variability in daily iodine levels (Borak, 2005). For instance, for a population to be considered iodine deficient by the WHO definition, the median urinary iodine concentration must be below 100 ug/L and at least 20% of the population must be below 50 ug/L. Borak notes that much of the confusion in the interpretation of NHANES data comes from this seemingly high number of people that may be below 50 ug/L urinary iodine. He explains "...the reason for such seemingly inconsistent criteria is the need to anticipate potentially large variability when iodine levels are measured in spot urine samples" (Borak, 2005).

Third, despite the presence of perchlorate in breast milk, studies have shown that this level of perchlorate does not cause adverse effects in children (Tellez et al., 2005; Amitai et al., 2007). Moreover, these studies have all shown doses of perchlorate that are below the NOEL from Greer et al. (2002), and are therefore insufficient to inhibit iodide uptake by the NIS. If a person, or a population, is iodine insufficient, reducing perchlorate, at environmental relevant concentrations, will not improve iodine insufficiency. Supplemental iodine will (e.g., iodized salt) reduce or negate iodine insufficiency.

Fourth, the NRC perchlorate panel concluded that iodide deficiency if it even exists in the U.S., is mild and "...perchlorate exposure most likely would not exacerbate it" (NRC, 2005). Finally, the RfD is a conservative health protective value that is based on a NOEL with the addition of a safety factor to account for the most sensitive individuals. The HRL, which is even more conservative than the RfD, was calculated based on pregnant women and was verified using PBPK modeling to consider whether the HRL would be protective of other sensitive subpopulations, including infants, by factoring in body weight, water intake, and food intake.

Response: The data underlying the definition of iodide uptake inhibition as a precursor effect and the relationship of iodide uptake inhibition to the continuum of adverse outcomes reflects an understanding of effects in adults; it may not reflect the relationship of the precursor event to adverse outcomes in neonates and infants, who may not have iodide stores sufficient to offset the effects of reduced iodide uptake. The less resilient neonatal and infant system makes the exposure

gap between a precursor event (iodide uptake inhibition due to perchlorate) and reduced T3/T4 levels likely to be narrower than for adults, and in fact, the distinction between the two may be blurred for the very young (Greer et al., 2002; Savin et al., 2003; van den Hove et al., 1999). The NRC noted that, "[T]he minimal prolonged decrease in thyroid hormone production that would be associated with adverse health effects is not known; any decrease is potentially more likely to have adverse effects in sensitive populations (people with thyroid disorders, pregnant women, fetuses, and infants) but data are not available to determine the magnitude of the decrease needed to cause adverse effects in those populations."
With regards to conclusions of the NRC panel on the effects of perchlorate exposure EPA believes the NRC appropriately based the RfD on iodide uptake inhibition to the thyroid, for the reasons discussed in its report.

Comment: V. EPA's Methodology to Support the HRL Could be Explained More Completely

In the preliminary determination, EPA puts forth a methodology to measure the contribution of food to total exposure by combining two nationally- representative data sets. The best available scientific understanding supports EPA's use of actual data as opposed to default parameters to derive the RSC. As EPA set out in its 2007 notice, EPA has multiple options to estimate the contribution of food to total exposure. At that time, the PSG presented analysis of the scientific merits of these options. The conclusions in those comments remain valid: no matter which scientifically-valid approach EPA takes, EPA can and should conclude that a national drinking water standard would not yield a meaningful reduction in human health risk.

The approach outlined in the proposed determination and background document appears to have several limitations. These limitations may be omissions in the description and not in the methodology. While adequate to meet EPA's statutory obligation, we suggest that EPA's description could benefit from additional explanation. These suggestions are listed below.

* Sample Description. Both UCMR and NHANES are nationally representative samples. The sample frame and the sample weights are published and have undergone peer review. EPA takes a subsample from these data sets and compares them for its analysis. EPA's analysis could benefit from a more complete description of the characteristics of these subsamples. Further description would assist the public especially since EPA is comparing absolute levels of perchlorate measured in drinking water and in total exposure. Many factors could influence absolute amounts of food and drinking water consumption in a person at a given time such as climate, weight, age, and income. It is unclear from the analysis how the sample populations in Bins I, II, and III compare on these characteristics. For example, if the Bin III (and more importantly, its subgroups) population has a larger Body Mass Index (BMI) than the average US population, the sample population may consume more food than average. In this scenario, Bin III's absolute amount of perchlorate may be larger than the typical person in the US.

* Sample Population Size. The importance of describing the sample in more detail is magnified by the small number of individuals in the sample results EPA uses. EPA uses the 90th percentile result from the 98 pregnant women in Bin III. EPA has not described the statistical relation of this sample to the US population. In addition, based on the shape of the distribution described in Blount (2006), the upper percentile results must be driven by relatively few observations. In other words, the analysis relies on the results from just a few women of unknown relationship to the whole US population or the subpopulation of pregnant women.

Viewed in this way, EPA's analysis is a convenience, non-statistically representative sample that is comparable to other study populations in Greer et al. (2002), Pearce et al. (2007), Tellez et al. (2005), and Amati et al. (2007). These studies all show that for total doses in excess of the RfD, there are no measurable adverse health effects on the study populations, including sensitive populations. Therefore, while EPA constructs this study population to estimate an RSC, it primarily reinforces the PSG's position that no effects occur below the RfD even for sensitive subpopulations. Until EPA provides more description of its study population, its advantages over the other published, peerreviewed studies is unclear.

* Temporal Comparison. In its background document, EPA describes how it linked the two study populations in the dimension of space - EPA assigned individuals to the bins based on whether a drinking water system in the county reported any single detection of perchlorate. EPA notes, but does not fully describe, how EPA handled temporal associations. The UCMR data was gathered from 2000 to 2005 according to EPA. The NHANES survey was conducted during 2001 and 2002. It is not clear whether EPA only used the UCMR counties that reported detections in 2001 and 2002 or all years in the UCMR dataset. This consideration is important since many systems that detected perchlorate did not do so routinely. If EPA used the UCMR data from all years, EPA should describe how many individuals in the Bin III subgroups lived in counties with an actual detection during the 2001-2002 time period.

Additionally, on the NHANES sample, it is unclear how EPA adjusted the food consumption data to reflect seasonality. People eat different foods at different times of the year. While NHANES adjusts for this fact in its study design, it is unclear how and if EPA did so in its subsample. For example, if 50 percent of the pregnant women in Bin III were surveyed by NHANES in the summer, the food consumption patterns (and the distribution of absolute levels of perchlorate) would be different than if only 25 percent were sampled during that time.

* Concentrations below Detection Limits Assumed to be Zero. EPA notes that one limitation is that the analysis assumes that all detections below 4 ppb are assumed to zero. EPA states:

It is uncertain how the 4 ug/l detection limit in the UCMR might affect the assignment of NHANES to Bin III. However, EPA believes that the classification is reasonable and that it is unlikely that any false negatives would significantly change the findings because there is a low frequency of occurrence above the method reporting limit (less than two percent of all samples had detects), it is reasonable to assume that there would be a corresponding low frequency of occurrence below it if at all. (EPA envisions a scenario with a high frequency of occurrence at very low concentrations unlikely). (pg 13)

First, while the misclassification problem among bins is interesting, it is clear how the detection limit will bias the results within Bin III. Bin III is supposed to represent individuals that only receive

perchlorate through food. EPA uses the Bin III results to calculate the dose received from food. If some of this dose actually derives from drinking water, EPA is overestimating the dose from food, underestimating allowance available from drinking water, and underestimating the HRL.

Consider this scenario. In the pregnant women subgroup of Bin III, the 98 pregnant women have an average estimated perchlorate intake of 0.123 ug/kg/day. In the analysis, EPA assumes the water contribution is zero. Suppose the true water concentration for the 98 women is 1/2 the detection limit (or 2 ug/l), a common EPA assumption in risk assessments and other 13 drinking water exposure scenarios. The women then receive a dose of 0.057 ug/kg/day from drinking water. This amount is 46 percent of their total dose. Their estimated food dose is correspondingly lower, the relative source contribution would be lower, and the HCL should be greater than 15 ppb. While the 1/2 the detection limit is merely an assumption, it illustrates the main point - the censoring of the data due to the detection limit can have a large effect on the Bin III results.

This effect will only be large if a significant proportion of the Bin III population has concentrations of perchlorate in drinking water below the levels of detection. EPA finds "high frequency of occurrence at very low concentrations unlikely." If "high" means 90 percent of the population, this scenario is unlikely.

Table 2 in the proposed determination shows the estimated population served with at least one sample above the detection limit has an exponential shape to it (each time the concentration is cut in half, the estimated population exposed at that level doubles.) It is reasonable to assume that this relationship continues below the detection limit. By assuming all people in Bin III receive no perchlorate from drinking water, EPA overestimates the concentration from food and creates an overly conservative HRL.

In summary, EPA's approach is scientifically appropriate in using actual observed data to estimate the RSC and the HCL. All approaches have limitations; however, any limitations in EPA's analysis have to be viewed in context of the extensive body of literature on perchlorate's mode of action and measured effects in humans. When EPA's analysis is viewed in the context of the NAS findings and other published studies, EPA's analysis is one more way to demonstrate that total exposure to perchlorate in the US is common and without adverse effect. EPA's analysis is more than adequate to demonstrate that perchlorate does not occur at a frequency and level of health concern to warrant an NPDWR.

Response: See response to comment code 5220 for a discussion of the alternative Health Reference levels. Your observations regarding some limitations of the Huber et al. study are correct, and as you note changes in dietary habits or food sources over a year or the possibility of small water contribution to what is considered food-only source would change results in a minor way. Because NHANES collects samples at different times of the year the result we obtained will be applicable for the entire year, and small changes would not be significant from a health standpoint. The gap in the data of course is the lack of information on children less than 6 years old which has become a focus of concern.

EPA Comment Code: 5220

Comment: However, in the October 10th Preliminary Regulatory Determination, EPA decided not to set a federal MCL for perchlorate. This was based upon the establishment of a drinking water Health Risk Limit (HRL) of 15 ug/L as the bright line for evaluating how many people would be exposed to concentrations of concern. The numerical target of 15 ug/L can be questioned on a number of fronts given that other recent derivations by states governments have yielded drinking water targets of 2 to 6 ug/L (New,Jersey, Massachusetts, California). The EPA assessment supporting the 15 ug/L HRL was reasonable in some regards (e.g., the mannner in which the relative source contribution was derived) but is not well justified when it comes to the level of exposure allowed for breast and bottle- fed infants. EPA's own assessment puts this early life exposure at 2 to 5 times greater than the Agency's RfD, with this justified by the use of an exploratory pharmacokinetic model which has no possibility of being validated for children. Given that this a key population to protect, it is essential that the HRL be set such that the RfD is not exceeded in this group. This is especially the case given that the health protectiveness of the RfD has been questioned by the CDC study, which shows quite clearly that effects on thyroid hormone status are possible at levels of perchloratc below the RfD in adult women (Blount et al. 2006).

The establishment of a lower HRL, more in line with recent derivations within several states, would yield a considerably larger public health impact than what was put forth by EPA in its draft determination. Therefore, this needs to be carefully reassessed. Our recommendation for a reassessment is in line with EPA's own Science Advisory Board which called EPA's decision premature stating that; "Given perchlorate's wide occurrence and well-documented toxicity to humans, the Science Advisory Board strongly believes that there must be a compelling scientific basis to support a scientific determination not to regulate perchlorate as a national drinking water contaminant" (SAB letter, November 5, 2008).

Comment: Moreover, the Environmental Protection Agency has not presented any sound scientific evidence that sufficiently explains why the previous health reference level (HRL) that supports a drinking water equivalent of 15 ug/L is inadequate. The 15 ug/L HRL was established from scientifically supported literature and based on the most sensitive sub-population, plus an added ten-fold safety factor.

We understand that the scientific evaluation of perchlorate has become complicated over the past few years but believe that there remains a significant need for more comprehensive scientific evaluation and debate.

We appreciate your attention to our concerns.

Sincerely, Richard Nieuwenhuis President

Water Docket Environmental Protection Agency Mailcode 2822T 1200 Pennsylvania Avenue Washington, DC 20460

RE: "Drinking Water: Perchlorate Supplemental Request for Comments" 74FR159:41883, August 19, 2009

Dear Sir/Madam:

The Chemistry Council of New Jersey (CCNJ) represents the interests of over 100 manufacturers in the business of chemistry in the Garden State. Our mission is to advance members' interests, operational and environmental excellence, science education and community outreach.

The CCNJ appreciates this opportunity to provide comments on the above referenced public notice regarding alternative approaches to the interpretation of scientific data relevant to a regulatory determination for perchlorate in drinking water.

CCNJ has several concerns about this issue. We believe that good public policy must be developed and proposed using sound, proven scientific data and presented in a manner which the public can understand and make informed judgments to determine application and appropriate risk prevention practices.

Repeated scientific investigation, including a landmark National Academy of Sciences (NAS) review, result in a clear and consistent conclusion: low levels of perchlorate are not dangerous to public health. We should not ignore this data. Without the presentation of supporting scientific literature

justifying alternative analysis, it becomes difficult for EPA to demonstrate why this alternative would support a science based regulatory determination under the Safe Drinking Water Act (SDWA). Not only has EPA not presented any justification for an analysis based on an alternative health reference level that uses water intake and body weight measurements at specific life stages, but EPA has also not presented any scientific evidence that indicates why the previous HRL that supports a drinking water equivalent of 15 ppb, based on the most sensitive subpopulation, with an added ten fold safety factor and derived from the scientifically supported literature is inadequate.

Response: See response to comment ID 28799 under comment code 5220.

Commenter Name: Jennifer Sass

EPA Document ID: EPA-HQ-OW-2009-0297-0412
EPA Comment ID: 28799
EPA Comment Code: 5220

Comment: EPA tried to support its conclusions that a 15 ppb HRL is safe by avoiding reference to the RfD, and instead referring to the level of inhibition of radioactive iodide uptake (RAIU) on which the NRC report (NRC, 2005) based its recommended RfD.[FN32: 73 Fed. Reg. at 60277.] EPA cannot shift its evaluation of acceptable exposure estimates to a discrete biological endpoint that leads to exceedances of the RfD.

Response: In the October 2008 preliminary regulatory determination, EPA had derived a single HRL of 15 µg/L based upon the RfD, an estimate of perchlorate exposure from food for pregnant women, and traditional adult body weight (70 kg) and drinking water consumption (2 L/day) values. This single HRL was derived to reflect exposure to a pregnant woman and her fetus, which the NRC identified as "the most sensitive population."
Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA has developed potential health reference levels (HRLs) for perchlorate for purposes of this regulatory determination. HRLs are not final determinations about the level of a contaminant in drinking water that is necessary to protect any particular population. Rather they are benchmarks against which EPA compares the concentration of a contaminant found in public water systems to determine if it is at levels of public health concern.

Comment: RESPONSE TO REQUEST FOR COMMENTS ON THE HRL

In simple terms, the HRL is the maximum tolerable amount of perchlorate that could be in drinking water, considering that perchlorate is also in food, and still keep daily consumption levels from exceeding the RfD. The 2008 proposed HRL of 15 ppb was calculated as follows: For all populations, including pregnant women, EPA determined that the RfD is 0.7 ug/kg/day. This value is posted on the IRIS database based on recommendations from a committee of the NRC. EPA reports that for pregnant women, exposure to perchlorate from food is 0.263 ug/kg/day at the 90th percentile (based on data from a national food survey), representing nearly 38% of the RfD, thus leaving an relative source contribution (RSC) for water of 62%.[FN43: 73 Fed. Reg. at 60276)] This is equivalent to 0.437 ug/kg/day from water, assuming an average body weight of 70 kg, and a daily water consumption of 2 L (90th percentile adult water consumption). That is, 0.437 ug x 70 kg body wt. = 30.6 ug perchlorate in 2 L (the daily consumption amount). This is 15 ug/L, or 15 ppb, the HRL proposed in the October 2008 FR notice.

Response: No response necessary to this summary of EPA information.

EPA Comment Code: 5220

Comment: Because the RfD was based exclusively on the dose-response calculations derived from the Greer et al study, then the HRL also relies on that data to derive a maximum allowable level of drinking water contamination. The derivation of a health-based standard for perchlorate should reflect the best available data, including published data collected and analyzed by the CDC and described by Blount (2006) and Blount (2007).[FN43: Blount BC, Valentin-Blasini L, Osterloh JD, Mauldin JP, Pirkle JL. Perchlorate exposure of the US Population, 2001-2002. J Expo Sci Environ Epidemiol. 2007 Jul;17(4):400-7. Epub 2006 Oct 18. Blount BC, Pirkle JL, Osterloh JD, Valentin-Blasini L, Caldwell KL. Urinary perchlorate and thyroid hormone levels in adolescent and adult men and women living in the United States. Environ Health Perspect. 2006 Dec;114(12):1865-71.] As noted above, these data have the following advantages over the Greer et al data:

1. Although the CDC data are from a cross-sectional analysis, because the survey includes a large number of individuals, the variability represents random error, not bias, and the data are likely to be representative of chronic perchlorate exposure;

2. The number of individuals included in the CDC study are sufficient for the specific analysis of a sensitive subpopulation defined as women with low iodine intake;

3. A benchmark dose (BMD) analysis of perchlorate-related modulation of serum thyroid hormone concentrations is feasible; and

4. Perchlorate exposures, as measured by urinary perchlorate concentration, corresponding to the benchmark dose low (BMDL) can be converted to an estimated dose in mg/kg-day, that can be used as the point of departure for the derivation of both the MCL and HRL.

The mean for total serum T4 concentrations in women is 8.27 ug/dL and the 25th percentile of perchlorate exposure (equivalent to 1.6 ppb perchlorate in urine) is associated with a 10% drop in total serum T4 in women with low iodine intake.[FN44: Blount BC, Pirkle JL, Osterloh JD, Valentin-Blasini L, Caldwell KL. Urinary perchlorate and thyroid hormone levels in adolescent and adult men and women living in the United States. Environ Health Perspect. 2006 Dec;114(12):1865-71.]

EPA Comment Code: 5225

Comment: Enclosed are my comments on your approaches for deriving HRLs on Perchlorates and other chemicals in our drinking water.

4.

a. No, I do not feel EPA appropriately took into account specific and appropriate exposure values for all potentially sensitive life stages, including infants, children and the fetuses of pregnant women. Any exposure to these type of chemicals should be eliminated and controlled to protect Americas' drinking waters. The 70 kg body weight and 2 liter per day consumption used for past regulatory determinations are grossly inappropriate levels to consider safe.

b. I feel none of these these values are low enough to be appropriate levels to determine health concerns against which to compare the levels of perchlorates found in public water systems. I urge you to adopt the smallest exposer levels considered or preferably lower them to no (0) exposure at all.

c. I feel the EPA did not use the best available and most appropriate data to estimate alternative HRLs in Table 2 because you cannot control how much water any one person consumes or the amount of perchlorate exposure from other sources. No, your drinking water ingestion rates in Table 2 do not take into account the life stages (birth to 6 months, and women ages 15-44) and does not provide an accurate representation of the exposure to the most vulnerable life stages because you cannot control how much water any one person consumes or the amount of perchlorate exposure from other sources.?

Response: See response to comment code 5220 for a discussion of the HRLs. Regarding health implications of exposures above the HRLs, the data underlying the definition of iodide uptake inhibition as a precursor effect and the relationship of iodide uptake inhibition to the continuum of adverse outcomes reflects an understanding of effects in adults; it may not reflect the relationship of the precursor event to adverse outcomes in children. We know that thyroid hormone status in neonates and infants is less resilient than in adults. That is, in general, neonates and infants may not have iodide stores sufficient to offset the effects of reduced iodide uptake. Half-lives for circulating hormones in neonates and infants are shorter than for adults, making neonates and infants less able to maintain stable hormone levels in the face of a chemical insult. The less resilient neonatal and infant system makes the exposure gap between a precursor event (iodide uptake inhibition due to perchlorate) and reduced T3/T4 levels likely to be narrower than for adults, and in fact, the distinction between the two may be blurred for the very young (Greer et al., 2002; Savin et al., 2003; van den Hove et al., 1999). The NRC noted that, "[T]he minimal prolonged decrease in thyroid

hormone production that would be associated with adverse health effects is not known; any decrease is potentially more likely to have adverse effects in sensitive populations (people with thyroid disorders, pregnant women, fetuses, and infants) but data are not available to determine the magnitude of the decrease needed to cause adverse effects in those populations." The additional sensitivity of these groups to perturbations in thyroid hormone levels, and the uncertainty about the point in the continuum of effects at which adverse effects occur are important considerations in concluding that perchlorate exposures above the RfD are likely to have an adverse effect on the health of sensitive life stages. Therefore, we do not agree with those commenters who stated that levels of perchlorate in drinking water that result in exposures greater than the RfD are not levels of public health concern.

EPA Comment Code: 5225

Comment: Comments on the Health Reference Level (HRL) Issues - While we are generally comfortable with the development of the alternative HRLs in Table 2 (page 41888), the key question is: what HRL should be used as the basis of the regulatory determination? This is where we have some concern. Ideally, the regulation of a contaminant would be targeted at the most sensitive subpopulations, no matter how small the subpopulation. However, we must also be cognizant of resource limitations and practical constraints. It may not be feasible to protect very small subpopulations with a general regulation but rather, it may be more appropriate to use other risk reduction approaches to target small groups that may have special sensitivity. We cannot recommend a specific HRL without a full understanding of the implications on the burden for water systems and states, which these data do not provide. The HRL of 15 ug/l, derived using the traditional approach, is a good starting point and would cover a large percentage of the population. In addition, EPA should evaluate a range of HRLs between 15 and 4 ug/l in connection with more sensitive subpopulations. The Agency could then consider these values, in combination with occurrence data, in order to determine the populations that could be protected by regulation and whether regulation at these lower levels would present a "meaningful opportunity for health risk reduction", as required by the Safe Drinking Water Act.

Comment As noted in his 9 March 2009 memorandum on Scientific Integrity, President Obama recognizes that science and the scientific process must inform and guide Administration decisions on a wide range of issues, including improvement of public health, protection of the environment. The memo underscores the importance of scientific integrity by further noting that if the public is to trust the science and scientific process informing public policy decisions there should be transparency in the preparation, identification, and use of scientific and technological information in policymaking. In embracing the President's commitment to scientific integrity, Administrator Jackson notes in her 9 May 2009 memorandum to EPA employees that the Agency's regulatory decisions should include a full explanation of the science issues addressed by the Agency, the data relevant to those issues, and the interpretations and judgments underlying the Agency's scientific findings and conclusions.

Suggested Action, Revision and References (if necessary) To ensure consistency with Administration and Agency commitments to scientific integrity, the following issues need to be considered in a transparent and scientifically defensible manner prior to the determination of any Health Reference Level (HRL), because they can impact the conclusions drawn by the EPA in the potential for health risk reduction for perchlorate in drinking water. While these issues do not address all requests for comments on alternative approaches, they focus on issues that will have the most significant impact on the determination and acceptance of an alternative HRL. The main issues associated with the alternative approaches presented by EPA (2009) include the following: 1. The lack of transparency and assurance of quality in the determination of alternative HRLs. 2. Inadequate characterization of exposure to sensitive subgroups, specifically infants and the fetuses of pregnant women. 3. A lack of justification for elimination of the PBPK models from consideration in the determination of an HRL. 4. Recommended applications for the PBPK models in the development of an HRL.

Category* S, M

Response: EPA believes that it has been consistent with Administration and Agency commitments to scientific integrity. The August 2009 notice clearly discusses the basis for alternative health reference approaches and that EPA was re-evaluating how best to incorporate PBPK modeling analysis into its evaluation of perchlorate, if at all.

Comment The current documentation of the suggested alternative HRLs based on body weight and water consumption of other life stages is inadequate. The development of this alternative approach relies heavily on the FDA total dietary survey (Murray et al. 2008) and the first Unregulated Contaminant Monitoring Regulation (UCMR 1). While these studies are well conducted and provide a significant resource for information, the documentation provided is not sufficient to demonstrate their application, nor to insure their reproducibility by other parties.

Suggested Action, Revision and References (if necessary) To insure clarity it is recommended that sufficient documentation be provided. Under the Data Quality Act (Section 515 of the Treasury and General Government Appropriations Act of 2001 (PL 106-544, H.R. 5658), Federal agencies are charged with ensuring the quality, integrity, and objectivity of information provided. See also comment #s 11 and 14.

Category* E, M

Response: EPA disagrees that the documentation of the suggested alternative HRLs is inadequate. In the October 2008 and August 2009 notices, EPA presents in detail the Unregulated Contaminant Monitoring Rule data as well as the Food and Drug Administration's Total Diet Study in 73 FR 60269–72. EPA has described how those studies have been used in deriving health references. EPA believes these are the best available peer reviewed data and that they have been applied in a reproducible manner.

Comment By removing the PBPK models from consideration, the agency has effectively removed consideration of the age-dependent variations in biology, and is apparently assuming that all differences may be accounted for by addressing the differences in exposure. There are many age-dependent differences, including exposure, clearance, protein binding, and NIS capacity, as well as extrathyroidal sites of iodide inhibition (placenta, milk) that influence perchlorate toxicology. The models were developed using specific data to quantify these differences, and while uncertainty may exist in specific parameter values, it is certainly better to estimate parameter values from data rather

than ignoring their existence. Factors such as clearance, maternal-fetal transfer, and extrathyroidal inhibition cannot be addressed in a standard analysis based on adjusting Points of Departure (PoDs) by exposure differences. Indeed, in the current proposal, the uncertainty associated with these parameters is added to other uncharacterized uncertainty, which does not improve estimates of risk.

The alternative HRL approach represents, in fact, a decision to become less informed about the processes governing potential increased risk to the sensitive populations, giving the impression that it is better to ignore the uncertainty related to real biology than to attempt to account for it.

Suggested Action, Revision and References (if necessary) Instead of using the 90th percentile for exposure and an RSC, a more mathematical approach should be used to assess uncertainty in model predictions (i.e., Monte Carlo). This would help define expected ranges of inhibition after taking into account both variability in exposure and intraspecies variability in biological parameters. Not only would this be a more quantitative way of accounting for uncertainty in exposure, but it would also address commenter's concerns about the model parameter uncertainty and transparency.

Category* S. M

Response: EPA disagrees that by not using the PBPK model the Agency is deciding to become less informed. See response to comment ID 20432 under comment code 5220 for a discussion of EPAs decision not to utilize the PBPK model.

Comment: Comment No. 11

Section III. B. 3. Alternative Approaches for Calculating HRLs

Page & Paragraph Page 41888 Column 1 Para 1

Comment Example of comment # 2: The document relies on information to characterize ingestion to early life stages, which represent a sensitive subgroup, based on sample sizes that do not meet minimum data requirements. While EPA (2009) states that these are the best available data, there is no indication that a comprehensive literature search was conducted to determine if additional data could be used to supplement or validate the data provided.

Suggested Action, Revision and References (if necessary) It is recommended that a comprehensive literature search be performed and documented.

Category* E

Comment No. 12

Section III. B. 3. Alternative Approaches for Calculating HRLs

Page & Paragraph pg 41888 Column 1-3

Comment Based on the EPA's analysis of percent radioactive iodide uptake (RAIU) inhibition estimated with the PBPK model (Table 8, EPA 2008), the NRC (2005) identified the 7-day old breast-fed infant and the fetus of the pregnant woman at 40 weeks as the most sensitive subgroups. Yet, in their attempt to develop alternative HRLs based upon body weight and water consumption, which appears to be the only alternative presented, EPA (2009) has not adequately characterized exposure to perchlorate by these subgroups. The Relative Source Contribution for perchlorate from food for the birth to 12 month life stages (Table 2, EPA 2009) is based on information provided in the FDA Total Dietary Survey (Murray et al. 2008). The EPA (2009) states that because no information was available from the TDS for the life stages from birth to 6 months of age, estimates for the nearest age range (6-12 months) was used. The intake from food provided by Murray et al. (2008) largely results from the determination of perchlorate in baby food and commercial formula ingested by children aged 6-11 months. From birth to six months, however, baby food would not be a significant portion of the diet. If intake is assumed to be mainly from commercial formula, the RSC may be similar, but this is a major uncertainty. Furthermore, intake from breast milk is not addressed at all using the HRL approach. It is not reasonable to assume the same dietary ingestion in the newborn ingesting breast milk alone, and the child that is eating solid food. It is, in fact, impossible to define perchlorate exposure in the breast-fed infant or the fetus, using this revised approach for defining an HRL.

Suggested Action, Revision and References (if necessary) It is recommended that the alternative HRLs not be used to estimate risk for this sensitive subgroup.

Environmental Protection Agency (EPA). 2008. Drinking Water: Preliminary Regulatory Determination on Perchlorate. Federal Register 73(198):60262-60282.

National Research Council (NRC). 2005. Health Implications of Perchlorate Ingestion. National Academies Press, Board on Environmental Studies and Toxicology. January, 2005.

Category* S. M

Response: Regarding the recommendation to conduct and document a comprehensive literature search on information to characterize ingestion to early life stages, EPA believes that it did just that in developing EPA's "Child-Specific Exposure Factors Handbook." The information in the Handbook represents the best available peer reviewed data on drinking water ingestion rates for various life stages.

Regarding the recommendation that alternative HRLs not be used to estimate risks for sensitive groups, EPA strongly disagrees. The NRC (2005) identified fetuses of iodide deficient pregnant women are the most sensitive life stage and also identified infants and developing children as sensitive life stages. . EPA estimates that at least 5.1 to 16.6 million people are served by PWSs, for which we have data, that have perchlorate contamination.

EPA has determined that a NPDWR for perchlorate may reduce perchlorate exposures for these infants, children, and pregnant women to levels below the RfD, and therefore believes that this

perchlorate exposure reduction presents a meaningful opportunity for the reduction of health risks for persons served by PWSs.

EPA has made this determination based on a consideration of the best available peer reviewed science and data collected in accordance with accepted methods related to perchlorate occurrence in drinking water, the presence of perchlorate in foods, and the health effects of exposure to perchlorate.

Comment: Comment No. 13

Section III. B. 3. Alternative Approaches for Calculating HRLs

Page & Paragraph Page 41888 Column 1-3

Comment The major problem with the current approach is the lack of characterization of exposure by those sensitive subgroups identified by NRC (2005): the 7-day old breast fed infant and the fetus of the pregnant woman at 40 weeks of gestation. The available dietary surveys and drinking water ingestion rates are incapable of providing a means to determine potential intake for these sensitive subgroups.

Suggested Action, Revision and References (if necessary) Incorporation of a PBPK model at this step would provide a reasonable method for estimating maternal transfer of perchlorate. One of the major strengths of the PBPK models is that they provide a platform for estimating fetal and infant dose using biological data on transfer rates and pharmacokinetic data in both the animal and human. These models have been tested against human iodide data, and when available, perchlorate data. It is true that the data sets available for validation were extremely limited. However, even limited data are better than the complete lack of data available to support the new approach. Derivation of an HRL for the breast fed infant and fetus needs to consider such complex biological processes as placental transfer, active uptake in the mammary gland, and extrathyroidal inhibition. In 2008, the PBPK models were used to address these issues. The current approach does not utilize the PBPK models, and in the process does not consider what is known about the important biological determinants of perchlorate transfer to the fetus and infant, the identified sensitive subgroups.

Comment: Comment No. 15

Section IV. Consideration of Studies Published Since EPA Adopted the NAS RfD for Perchlorate

Page & Paragraph Pages 41889 41891

Comment EPA requests comment on whether EPA used the best available and most appropriate data to estimate alternative HRLs in Table 2.

The HRL it is too simplistic and does not take into account the full range of scientific knowledge regarding coexposure to chemicals known to also bind to the NIS receptor. For example, it does not allow taking into account other relevant issues concerning thiocyanate and nitrate co-exposures. It also does not consider factors such as potential differences in the perchlorate "half-life" compared to thiocyanate and nitrate, and comparison of thyroid hormone effects.

Suggested Action, Revision and References (if necessary) Evaluate the above referenced (see Comment #10) human sensitive subpopulation data using direct measurement of biological fluids to derive the HRL for perchlorate considering the cumulative risk of other goitrogens (thyocianate and nitrate from dietary sources). These data should be considered for use in and/or validation of the EPA models.

Since not just perchlorate but also thiocyanate and nitrate are present in commonly ingested foods, as well as mother's and bovine milk, they all impact iodide uptake inhibition, and thus should be evaluated

Category* S

Response: While EPA acknowledges that nitrate and thiocyanate have the same mode of action as perchlorate, and that the effects of combined exposure to perchlorate, nitrate, and thiocyanate are additive, EPA does not believe there are sufficient scientific data currently available to assess and characterize the combined risk of these contaminants. EPA has committed to a drinking water strategy that outlines four principles to expand public health protection for drinking water (USEPA, 2010b). One of these principles is to address contaminants as groups. However, EPA does not believe that regulatory action to address perchlorate should be further delayed. Therefore, EPA intends to develop a proposed rule for perchlorate. At such time as a NPDWR is promulgated, EPA is required to review and revise, as appropriate, its drinking water standards at least every six years. Any revision must at least maintain or improve public health protection. When there are sufficient scientific data to assess the cumulative risks of perchlorate and other contaminants, EPA will review this information to evaluate whether any revisions of NPDWRs are appropriate.

Comment: The California agriculture groups submitting this letter appreciate the opportunity to comment on USEPA's August 19, 2009, Federal Register notice seeking comment on "additional approaches available for analyzing data related to EPA's perchlorate regulatory determination. The attached letter contains specific comments and information. Thank you for your consideration.

October 8, 2009

Mr. Eric Burneson Office of Ground Water and Drinking Water Standards and Risk Management Division Environmental Protection Agency 1200 Pennsylvania Avenue, NW Washington, DC 20460

Subject: California Agriculture Industry Comments on Docket Identification (ID) EPA-HQ-OW-2008-0692-Perchlorate Supplemental Request for Comments

Dear Mr. Burneson:

The undersigned California agriculture groups appreciate the opportunity to comment on USEPA's August 19, 2009, Federal Register notice seeking comment on "additional approaches available for analyzing data related to EPA's perchlorate regulatory determination." Since a national primary drinking water standard for perchlorate would directly impact public perception of the safety of agricultural commodities known to contain trace amounts of perchlorate, it is critical that EPA establish the appropriate science-based methodology before proceeding with a final regulatory determination.

The California agriculture industry is a $37 billion industry that produces more than 350 different crop and livestock commodities and generates an estimated $100 billion in related economic activity. California agriculture accounts for approximately 7.5% of all employment and supports more than a million on-farm jobs. California agriculture is also the leading global exporter of agricultural commodities, sending almost 20% of our agricultural production to foreign markets.

EPA's Proposed Alternative Health Reference Levels are Not Scientifically Justified and will Undermine Public Confidence in the Safety of Agricultural Commodities.

EPA's August 19, 2009, Federal Register notice states that the "additional alternatives under consideration could result in health reference levels which are much lower than the level identified in the October 2008 notice." This statement causes great concern for the California agriculture industry because it implies that exposure to trace amounts of perchlorate may be harmful to human health, when in fact, the rich body of scientific literature on perchlorate does not support this conclusion. It is well established that many agricultural commodities contain trace amounts of perchlorate, but these levels are widely recognized as being orders of magnitude below any level that may pose a risk of adverse human health effects. EPA's promotion of the alternative health reference level concept will needlessly rekindle public concern about the safety of agricultural commodities and will drive some consumers away from these products to avoid perchlorate exposure. The negative impacts on public health associated with such a shift in dietary habits will vastly outweigh the risk of harm associated with exposure to trace amounts of perchlorate.

Response: We appreciate your concern that food not be negatively impacted by evaluations of perchlorate in drinking water. The drinking water regulatory determinations health reference levels (HRLs) are calculated for public tap water and consider how much of the RfD is already taken by food exposure using a relative source contribution (see response to comment code 5220). Drinking water with perchlorate at levels less than the HRL may prevent the water-plus-food components of exposure from exceeding the RfD.

Commenter Name: Anthony Russo
Commenter Organization: Chemistry Council of New Jersey (CCNJ)
EPA Document ID: EPA-HQ-OW-2009-0297-0673
EPA Comment ID: 28690
EPA Comment Code: 5225

Comment: The Agency has sufficient data to show that perchlorate will not have an adverse effect on the health of persons at the levels expected in public drinking water systems, having based its RfD on a no observed effect level (NOEL) of a precursor to an adverse effect. Based on the available data, neither the first nor the second criteria of the SDWA are met.

EPA along with other experts including the NRC committee, ATSDR and OEHHA have all identified the most sensitive life stage as the fetuses of hypothyroid or iodine deficient pregnant women. The NRC committee determined that all sensitive subpopulations, including infants, would be protected by the drinking water equivalent of EPA's reference dose, 15 parts per billion (ppb). By proposing to base its calculation of alternative health reference levels (HRL) on specific life stages as opposed to the calculation based on the most sensitive sub- population (fetus), EPA would establish a scientifically unsupportable precedent that could then be applied to every other water contaminant for which and MCL has been established. EPA's calculation of alternative health reference levels (HRL) is not the best available science and thus runs contrary to EPA's duty under the Safe Water Drinking Act.

Response: See response to comment ID 28338 under comment code 5225.

EPA Comment Code: 5225

Comment: Alternative Health Reference Levels (HRLs) Based Upon Body Weight and Water Consumption of Other Life Stages

Studies have clearly proven that perchlorate is a naturally occurring chemical which is absolutely ubiquitous in the environment (Sanchez, Krieger et al. 2005; Snyder, Vanderford et al. 2005; Valentin-Blasini, Mauldin et al. 2005; Baier- Anderson, Blount et al. 2006; Blount, Pirkle et al. 2006; Blount, Valentin- Blasini et al. 2006; Snyder, Pleus et al. 2006; Dyke, Ito et al. 2007). The evidence of perchlorate's ubiquity is indisputable based on the recent NHANES and FDA Diet Study, which clearly demonstrated that perchlorate is present in the human diet; thus, increasing the challenge of demonstrating "a meaningful opportunity for health risk reduction for persons served by public water systems" through federal regulation of perchlorate in drinking water. Moreover, a recent study led by the Authority (Snyder, Stanford et al. 2009) has demonstrated that the use of hypochlorite for the disinfection of water may contribute perchlorate at levels within the range of HRLs shown in the FR. Therefore, we urge the EPA to consider the consequences of suggesting HRLs that do not consider epidemiological data that include in utero perchlorate exposure.

Response: EPA has carefully considered epidemiological data for perchlorate and determined that perchlorate meets SDWA's criteria for regulating a contaminant.

EPA agrees that perchlorate is naturally occurring. A 2006 study by a Texas Tech researcher (Dasgupta et al., 2006) identifies three principal sources of the perchlorate in the environment: its use as an oxidizer (rocket propellants, fireworks, flares and explosives), its presence in Chilean nitrate fertilizer, and formation via atmospheric processes.

Perchlorate is soluble and is taken up by plants along with water and nutrients. Its presence in food specifically is related to: (1) past propellant leakage into irrigation source water (e.g., Colorado River) which is applied to fields of crops that are distributed nationally; (2) smaller application of Chilean fertilizer to certain crops, i.e., principally in organic farming; and finally (3) rainfall and localized irrigation with ground water containing natural perchlorates.

Regarding the comment that the use of hypochlorite for the disinfection of water may contribute perchlorate at levels within the range of HRLs shown in the FR, EPA agrees that perchlorate has been found as an impurity in sodium hypochlorite which is commonly used by public water systems as a disinfectant to inactivate pathogenic micro-organisms. Reported concentrations of perchlorate introduced as a result of disinfection using sodium hypochlorite range from 1 ppb to 8 ppb (Greiner et al., 2008).

The extent to which perchlorate could be introduced into water from sodium hypochlorite depends on the operational practices of water utilities. In particular, the longer sodium hypochlorite is stored, the greater the concentration of perchlorate. These risk/risk tradeoffs can be addressed by implementing best management practices including storage in the dark at cool temperatures and use within 45 days of its manufacturing date. Perchlorate contamination resulting from sodium hypochlorite usage is more likely to occur in small drinking water systems than large.

October 8, 2009

Response to U.S. EPA, Drinking Water: Perchlorate Supplemental Request for Comments Docket ID No: EPA-HQ-OW-2009-0297

The approach taken by the Minnesota Department of Health (MDH) to develop health-protective guidelines for groundwater is consistent with alternative approaches considered by the U.S. EPA in the development of a drinking water guideline for perchlorate. The approach used by MDH to develop health risk limits (HRLs) for drinking water are much more aligned with the process outlined by the EPA in the August 19, 2009 Federal Register announcement than the process described in the December 2008 Perchlorate Interim Drinking Water Health Advisory report.

MDH supports EPA's August 2009 re-evaluation of the process used to develop drinking water guidelines for perchlorate. The previous approach used by the EPA in Interim Health Advisory Report was inconsistent with EPA risk assessment guidance. The use of the PBPK model appeared to be used to justify perchlorate exposure in infants and young children at levels above the RfD, an approach we would not endorse as health protective. Additionally, MDH was concerned by the lack of consideration of life stage sensitivities in the interim report, especially the absence of appropriate intake rates that were protective of sensitive subpopulations.

Response: See response to comment code 5220 for a discussion of the HRLs. See response to comment ID 20432 under comment code 5220 for a discussion of the PBPK model.

Commenter Name: Kate Sande

EPA Document ID: EPA-HQ-OW-2009-0297-0663
EPA Comment ID: 28702
EPA Comment Code: 5225

Comment: Our comments include a discussion about how MDH accounts for life-stages sensitivities when developing HRLs and how our approach compares with the alternative approaches EPA is considering for developing a perchlorate drinking water guideline. We have also included an example of how MDH would calculate a HRL for perchlorate using EPA's RfD of 0.0007 mg/kg-day and comments comparing the MDH drinking water guidelines and the alternative HRLs that EPA is considering (listed in Table 2, section III.B-3 of the Federal Register announcement).

Note: If this were a chemical review conducted by MDH, we would independently review the toxicological literature to derive our own RfD, which may not result in the same RfD adopted by EPA for perchlorate.

Section III, B-4.a - Request for comments about appropriate exposure values that consider sensitive life stages

Intake Rates MDH strongly supports EPA's reconsideration to use life-stage specific, high end (95th percentile) drinking water intake rates in the development of alternative HRLs. This is consistent with the approach used by MDH and EPA's recommendation to evaluate exposures that are shorter than chronic durations to account for higher intake rates than can occur during shorter periods (EPA, 2002). Additionally, MDH agrees with EPA's approach to use appropriate and relevant body weights for sensitive individuals when calculating intake rates.

To account for lower body weights and higher water intake rates by infants and young children during acute and short-term exposure durations, MDH uses an intake rate of 0.289 L/kg-day, based on the 95th percentile intake for an infant up to 3-months (EPA 2004 & EPA 2008a). The subchronic intake rate we use is 0.077 L/kg-day based on the time-weighted average of the 95th percentile intake from birth up to 8 years of age. The chronic intake rate used by MDH is 0.043 L/kg-day and is based on the time-weighted-average of the 95th percentile intake over approximately 70 years.

Response: See response to comment code 5220.

EPA Comment Code: 5225

Comment: Section III, B-4.b - Request for comments on the alternative HRLs in Table 2 and which would be an appropriate guideline

The formula used by MDH to calculate a non-cancer health protective drinking water guideline is:

Non-cancer Guidelineduration = (RfDduration x RSC x 1000) / Intake Rateduration

In the table below (Table 1) you will find the range of perchlorate concentrations in drinking water that MDH would derive based on our standard intake rates and relative source contributions described above for multiple exposure durations (acute, short-term, subchronic, and chronic). The drinking water concentrations derived below are for comparison purposes only and do no reflect current MDH guidance.

Table 1. MDH drinking water guidelines compared to EPA HRLs for perchlorate. [see PDF docket ID EPA-HQ-OW-2009-0297-0663]

*We adjusted the life stages used by MDH to conform to EPA's life stages listed in Table 2, section III.B-3 of the Federal Register announcement, however normally, MDH categorizes health guidelines by exposure durations as outlined in EPA's Reference Dose Process guidance (EPA, 2002).

**MDH does not calculate guidlines for each life stage listed in Table 2, section III.B-3 so we only included EPA HRLs that correspond to the life stages we consider at MDH. The EPA HRLs that were most appropriate for comparison were the ones calculated using the 95th percentile intake rates.

*** We felt a chronic MDH guideline provided the most appropriate comparison to EPA's HRL for pregnant women. The EPA HRL is higher than the MDH guideline because MDH used our default RSC of 0.2 and EPA used an RSC of 0.62.

Using the MDH HRL approach to calculate theoretical perchlorate drinking water guidelines resulted in a range of perchlorate concentrations of 1-3 ug/L which account for all life stages and sensitive subpopulations. Based on these concentrations, it is likely we would select 1 ug/L as the guideline to ensure the most sensitive individuals are protected. The EPA HRL of 2 ug/L for infants less than 3-months old is much more comparable to the MDH guideline than the interim HRL of 15 ug/L.

Section III, B-4.d Request for comments on the merits of the approach to derive HRLs for sensitive life stages based on the RfD combined the life stage specific exposure data

MDH agrees with the approach of developing HRLs based on the RfD combined with life stage specific exposure data. When developing an HRL, MDH conducts an independent review of the toxicological literature to develop an RfD and calculates a drinking water guideline using intake rates and relative source contributions that are protective of life-stage sensitivities.

MDH commends the alternative approaches described in the EPA Drinking Water: Perchlorate Supplemental Request for Comments announcement. They show that EPA is seriously weighing all life stages and highly exposed sensitive subpopulations in the development of a perchlorate HRL.

Thank you for the opportunity to comment. Please contact Kate Sande (651-201-4902) kate.sande@state.mn.us) with the Health Risk Assessment Section in the Environmental Health Division if you have any questions concerning these comments.

EPA Comment Code: 5225

Comment: B. Alternative HRLs Based Upon Body Weight and Water Consumption of Other Life Stages 4. Request for Comments a. EPA requests comment on whether the alternative HRLs described in this notice appropriately take into account specific and appropriate exposure values for all potential sensitive life stages, including infants, children and the fetuses of pregnant women (rather than the 70 kg body weight and 2 liter per day consumption used for past regulatory determinations).

Comment B.4.a.1: The available data do not indicate a differential effect on potentially sensitive subpopulations (fetuses and neonates). Consequently, alternative HRLs should not be developed for a postulated sensitive sub- population (fetuses and neonates). Development of alternative HRLs for a postulated sensitive sub-population should be predicated on reasonably rigorous scientific evidence demonstrating the need for such specificity. The current reference dose approach is generally believed to be sufficiently conservative to prevent health impacts with a margin of safety. We understand that the EPA does not find a need to reevaluate the current EPA-adopted RfD of 0.7 ug/kg-day, which is a conservative and health-protective reference dose that has a 10-fold uncertainty factor applied to the point of departure to account for differences between healthy adults and the most sensitive population: fetuses of pregnant women who might have hypothyroidism or iodine deficiency. Therefore, the development of alternate HRLs appears unnecessary because the health of the most sensitive sub-population (fetuses and neonates) has already been considered in setting and adopting the RfD. The need for application of a second tier uncertainty factor has not been demonstrated by the available studies. Application of an appropriately calculated relative source contribution (RSC) term, as was conducted during development of the January 2009 Health Advisory (HA), appears adequate and appropriate.

It is recommended that EPA support the design and collection of additional clinical data to determine if additional refinement of the RfD is needed to further address health protection of these sub-populations.

b. EPA requests comment on the alternative HRLs in Table 2 and which of these values would be appropriate levels of health concern against which to compare the levels of perchlorate found in public water systems.

Comment B.4.b.1: The available evidence in human populations indicates that all of the values identified in Table 2 are likely to be protective against adverse health effects. The NDEP notes that the reference dose calculation includes a 10-fold uncertainty, which was applied to the point of departure during development of the RfD to account for differences between healthy adults and the most sensitive population. NDEP believes that, based upon the currently available data, there is not adequate scientific basis at this time to depart from the health-protective Health Advisory level of 15 ug/L. This health- protective value already incorporates a 10-fold uncertainty factor to account for differences between healthy adults and the most sensitive population: fetuses of pregnant women who might have hypothyroidism or iodide deficiency.

c. EPA requests comment on whether EPA used the best available and most appropriate data to estimate alternative HRLs in Table 2. EPA specifically requests comment on the drinking water

ingestion rates in Table 2 (denoted by footnote c) where the sample size does not meet the minimum data requirements as described in the "Third Report on Nutrition Monitoring in the United States" (LSRO, 1995). Does aggregate life stages (birth to 6 months, and women ages 15 - 44) address sample size limitation and still provide an accurate representation of the exposure to the most vulnerable life stages?

Comment B.4.c.1: The fact that some of the data sets relied upon do not meet the minimum data requirements is one of the inherent problems in trying to regulate to a specific subpopulation rather than for the general population. If there was reasonably rigorous scientific evidence supporting the need for such special treatment to be protective against perchlorate health effects, an exception to minimum data requirements might be reasonable. However, the absence of such evidence, including considerable human data not supporting specialized sensitive receptor concerns, makes it inappropriate to incorporate these data for perchlorate regulation. The EPA-adopted reference dose of 0.7 ug/kg-day is a conservative and health-protective reference dose that has a 10-fold uncertainty factor applied to the point of departure to account for differences between healthy adults and the most sensitive population: fetuses of pregnant women who might have hypothyroidism or iodide deficiency. Consequently, additional adjustments to the RSC assumptions represent a second source of multiplicative conservatism that appear unnecessary to protect the sensitive sub-population.

Comment B.4.c.2: Separating the data into aggregate life stages (birth to 6 months, and women ages 15 - 44) is not necessary as it provides no discernable value in the calculation of an HRL, HA, or MCL. Steps such as these (separating life stages and grouping some life stages as aggregate life stages) might be justified if there were data demonstrating a valid concern for adverse health effects of perchlorate at or near the adopted Health Advisory.

d. EPA requests comment on the merits of the approach described here of deriving HRLs for sensitive life stages based on the RfD combined with the life stage specific exposure data and whether there are other approaches that may be useful for deriving HRLs.

Comment B.4.d.1: The merits of deriving HRLs as described in the August 19, 2009 Federal Register Notice include greater specificity of the risk-based calculations to the receptor population presumed to be of greatest concern, and perhaps reduced uncertainty in the degree of public health protection. However; the need for such an approach for deriving alternate HRLs for perchlorate that is more refined and conservative is not clearly supported by the available scientific evidence.

Response: EPA does not believe that an HRL of 15 ug/L adequately accounts for the greater exposure to perchlorate on a per body weight basis that infants and developing children have in comparison to adults. This greater exposure is not accounted for within the RfD as the 10-fold uncertainty factor accounts for greater sensitivity to the same exposure, not the fact that a child is likely to be exposed to a greater dose on a per body weight basis. See response to comment code 5220. Regarding the use of exposure data that meet minimum data requirements, EPA has relied on aggregated infant life stage data (i.e., birth to six months) that meet minimum data requirements for calculating the 90th percentile. EPA believes that the 90th percentile values within sensitive life stages appropriately account for variation in consumption on a per body weight basis and are protective of highly exposed individuals in these life stages.

EPA Comment ID: 28803
EPA Comment Code: 5225

Comment: a. Whether alternative HRLs take into account specific and appropriate exposure values for all potentially sensitive life stages

NRDC response: It is appropriate for the HRL to account for an infant's body weight, an infant's dietary intake and relative source contribution from water, and other contaminants that share a common mode of toxicity to perchlorate.

A bodyweight assumption appropriate for an adult female does not protect fetuses, infants or children. For example, infants consume almost six times more water (and therefore contaminants) than adults, on average, in proportion to their body weight. Therefore, it would not be appropriate to use an adult body weight when converting a reference dose into a drinking water standard that is protective of infants and children.

Many infants are breastfed for at least part of their first year of life, and perchlorate from both water and food does enter breast milk. Therefore, the appropriate choice for the breastfeeding scenario is to use an RSC value that reflects perchlorate the mother is taking in through food and drinking water since she is the source for the infant's breast milk.

Response: See responses to comment codes 5210 and 5220.

Comment: b. On which of the alternative HRLs in Table 2 would be appropriate against which to compare levels of perchlorate in public water systems

NRDC response: A level of perchlorate below 1 ppb is required to adequately protect vulnerable newborn babies and their recommended sole source of nutrition, breast milk.

In June 2006, the State of Massachusetts Department of Environmental Protection (MA DEP) and its scientific advisors (MA DEP/DPH Advisory Committee) "unanimously concluded that [the RfD] did not fully account for the uncertainties surrounding science's understanding of perchlorate toxicity and exposures."[FN46: MA DEP, "Update To 'Perchlorate Toxicological Profile And Health Assessment'" March 2006, page xii.] Following recommendations from their scientific experts, MA DEP finalized an enforceable perchlorate Maximum Contaminant Level for drinking water and a perchlorate Cleanup Standard of 2 ppb based on a review and assessment of all data available at the time. Likely because the Blount (2006) data were not yet available, the MA DEP drinking water and cleanup standards failed to consider the special exposure patterns of infants born to low-iodide women, whom we now know are among the most at-risk population based on both high exposure and vulnerability to permanent and severe neurological impacts. Therefore, an MCL must be below 1 ppb to be truly health protective.

Response: See response to comment code 5220.

Comment: PART I

EPA's Alternative HRL analysis. It is not clear whether EPA's new analysis resulting in new health reference levels (HRLs) is a one-time approach unique to perchlorate, due to a particular concern about certain subpopulations as noted in the 2005 National Academies of Science, National Research Council (NAS) report, or a new approach for determining contaminant levels that are of a concern for public health at various life stages based on EPA's 2005 Guidance on Selecting Age Groups for Monitoring and Assessing Childhood Exposures to Environmental Contaminants (2005 Guidance) that will be applied to future regulations.

If it is EPA's intent to apply the 2005 Guidance in this way for future regulations then EPA should clearly state this. AMWA also believes that the analysis should be sent to NAS for review since this is the first time that the 2005 Guidance has been applied in an analysis with implications for rule development, which would have major implications for future rulemakings.

The analysis could be specific to perchlorate as the contaminant is unique with respect to its health endpoints. As suggested in the peer review document of the drinking water health advisory for perchlorate, "...the biological impacts of perchlorate are very different from those for chemical compounds which have direct target organ toxicity and/or do not directly affect the availability of an essential element for which homeostasis occurs."

AMWA requests that EPA clearly explain the applicability of the alternative HRL analysis when issuing a final regulatory determination on perchlorate.

In addition, if the most sensitive subpopulation is the fetus of iodide deficient pregnant women, is the analysis showing new HRLs for children focused on those children who are iodine deficient? AMWA requests that EPA make this clear in its final determination. AMWA also recommends that EPA should make clear in its final regulatory determination whether it still considers the fetuses of pregnant women who are iodine deficient to be the most sensitive subpopulation.

Finally, AMWA asks that EPA discuss the significance of the lack of bioaccumulation of perchlorate in the body as noted in Greer et al., 2002 and NAS, 2005 after exposure and how this is accounted for in its exposure estimates in the HRL analysis.

Response: EPA believes that alternative HRLs described in the August 2009 notice appropriately take into account specific and appropriate exposure values for infants, children and the fetuses of pregnant women (rather than the 70 kg body weight and 2 liter per day consumption used for past regulatory determinations). This analysis is applicable to perchlorate because individuals at these life stages are particularly sensitive to the effects of perchlorate.

EPA will consider using life stage specific exposure factors where the best available science indicates life stages are particulary sensitive.

EPA's analysis of HRLs does not assume bioaccumulation of perchlorate.

EPA Comment Code: 5225

Comment: NOEL vs. NOAEL

The 2005 National Research Council report recommended an RfD of 0.0007 mg/kg by employing two margins of safety. The first was to use the point of departure as a conservative NOEL vs. a NOAEL. In addition, the report recommended applying an additional factor of 10 to protect all sensitive groups, including the fetuses of pregnant women with iodine deficiency and children and infants.

AMWA asks that EPA clearly explain the significance of the NOEL vs. NOAEL in the alternative analysis of HRLs, as it appears that the agency is compounding safety factors that already account for the sensitivity and variability between population groups.

Response: EPA has clearly and consistently explained the basis of departure for the perchlorate RfD using the NRC report language.

EPA does not believe that accounting for specific and appropriate exposure values for all potentially sensitive life stages, including infants, children and the fetuses of pregnant women "compounds," or "double-counts," the uncertainty factor that has already been applied.

Comment: 74 FR 41889: "EPA specifically requests comment on the drinking water ingestion rates in Table 2 where the sample size does not meet the minimum data requirements as described in the "Third Report on Nutrition Monitoring in the United States (LRSO, 1995)."

Response: AMWA believes that if the sample sizes for estimates of ingestion rates in Table 2 do not meet minimum data requirements set forth in CDC's LRSO, then they should not be used for HRL development that could be used as a basis for national policy.

Response: As EPA states in the August 2009 notice, for six life stages in Table 2 (birth to < 1 month, 1 to < 3 months, 3 to < 6 months, 16 to 18 years and 18 to 21 years and for pregnant women), the sample size used to estimate some of the drinking water ingestion rates (denoted in

Table 2 by foot note "c") do not meet the minimum data requirements as described in the "Third Report on Nutrition Monitoring in the United States." However, these are the best available data to characterize drinking water ingestion for these specific life stages. EPA also notes that these data clearly show the trend that drinking water mean ingestion rate on a per body weight basis increases as the life stage age decreases. Although the approach may have shortcomings, EPA interpolations/extrapolations are reasonable and in accordance sound and objective scientific practices.

EPA Comment Code: 5225

Comment: In closing, AMWA again urges EPA to have the alternative HRL and PBPK analysis reviewed as it is a new analysis that was developed by applying for the first time the 2005 Guidance. The potential precedent that will be set if these analyses are used in rulemaking will have significant ramifications for how future drinking water policy is developed. In addition, AMWA recommends that EPA consider all available science as well as the most recent occurrence data as it prepares its final regulatory decision.

Comment: Interpretation of the Physiologically-Based Pharmacokinetic (PBPK) Modeling

AWWA recognizes the value of using models for risk assessment purposes. The Agency, in response to concerns raised in October 2008, elected to reassess exposure to life stages and broaden the scope of "the most sensitive population" which previously had been defined by the National Research Council (2005) as "the fetuses of pregnant women who might have hypothyroidism or iodine deficiency." The assessment appropriately follows EPA's Guidance on Selecting Age Groups for Monitoring and Assessing Childhood Exposures to Environmental Contaminants (USEPA, 2005) which recommends the following 10 age groups be considered in exposure assessments for children.

- Less than 12 Months old: birth to < 1 month, 1 to < 3 months, 3 to < 6 months and 6 to < 12 months. - Greater than 12 months old: 1 to < 2 years, 2 to < 3 years, 3 to < 6 years, 6 to < 11 years, 11 to < 16 years, and 16 to < 21 years.

AWWA recognizes these important subpopulations, yet is troubled by the lack of recognition in the modeling efforts to incorporate the findings from the most recent and well designed epidemiological studies. These studies provide direct dose-response assessments that should be included into the Agency's modeling effort rather than making presumptive calculations for purposes of estimating a Health Reference Level (HRL) for each life stage examined. The majority of these studies have shown no adverse health effects to women of child bearing age, newborns, and school age children who were exposed to significant amounts of perchlorate via drinking water at levels below and above the EPA accepted Reference Dose (RfD) of 0.0007 mg/Kg-day), as well as to other goitrogens. These studies also address the request for comment regarding the use of the PBPK model to "explore the relative sensitivity of various life stages".

Comment: Alternative HRLs Based Upon Body Weight and Water Consumption of Other Life Stages

AWWA believes that it is unnecessary for the Agency to adjust for Relative Source Contribution (RSC) when calculating a HRL, since the RfD is based on a No Observed Effects Level (NOEL) and the Greer [FN7: Greer, M., Goodman, G., Pleus, R., and Greer, S. 2002. Health effects assessment for environmental perchlorate contamination: the dose-response for inhibition of thyroidal radioiodine uptake in humans. Environmental Health Perspectives, 110:927.] study only measured the incremental exposure to drinking water. The body of data on which the National Research Council (NRC) based their conclusions produced a No Observed Effects Level (NOEL) (not considered a No Observed Adverse Effects Level [NOAEL]because the biochemical changes measured were not considered adverse in and of themselves) of 0.007 mg/Kg-day. The NRC further recommended a total uncertainty factor of 10 for intraspecies extrapolation (the data were from humans), resulting in a recommended RfD of:

RfD = 0.007 / 10 = 0.0007 mg/Kg-day

The Agency [FN8: USEPA. 2005. EPA Sets Reference Dose for Perchlorate. New release dated 02/18/2005.
http://yosemite.epa.gov/opa/admpress.nsf/b1ab9f485b098972852562e7004dc686/c1a57d 2077c4bfda85256fac0 05b8b32!OpenDocument] accepted the NRC's RfD. Typically the RfD would be multiplied by the RSC for ingestion of drinking water to obtain a limit on exposure. However, this practice arose from the common use of clinical, epidemiological, or experimental animal studies in which individuals were exposed solely through the route of interest (e.g. ingestion of water). Given a sole route of exposure it is necessary to correct for the fact that individuals in the general

population would likely be exposed to a compound through multiple routes. As a result, the application of an RSC in the regulatory process is based on the (often unstated, but nonetheless implicit) assumption that the study population was NOT exposed through routes other than the one of interest, while the general population was exposed through ALL routes.

This assumption is not fully warranted in the case of perchlorate because the individuals in the Greer study maintained a normal diet during the period of the study.[FN9: Crawford-Brown, D., Raucher, B., and M. Herrod 2006. Inter-Subject variability of risk from perchlorate in community water supplies. Environmental Health Perspectives, 114:7:975.] Therefore, they should have been exposed to perchlorate from non-drinking-water routes at an Average Daily Rate of Intake (ADRI) value roughly equivalent to that of the general population that is the target of regulatory determinations. This is supported by the FDA's Total Diet Study [FN10: Murray, C.W III, S.K. Egan, H. Kim, N. Beru, P.M. Bolger. 2008. US Food and Drug Administration's Total Diet Study: Dietary Intake of Perchlorate and Iodine. Journal of Exposure Science and Environmental Epidemiology 18:571.] and the NHANES assessments [FN11: Blount, B.C., J.L. Pirkle, J.D. Osterloh, L. Valentín-Blasini, and K.L. Caldwell. 2006. Urinary perchlorate and thyroid hormone levels in adolescent and adult men and women living in the United States. Environmental Health Perspectives. 114:12:1865.],[FN12: Blount, B.C., L. Valentin-Blasini, J.D. Osterloh, J.P. Mauldin, and J.L. Pirkle. 2007. Perchlorate Exposure of the US Population, 2001-2002. Journal of Exposure Science and Environmental Epidemiology 17:400.], which suggests a ubiquitous exposure to perchlorate from various food sources. If this is the case, application of an RSC would in effect "double count" the influence of the non- drinking-water exposures, because the NOEL from the Greer study already reflected these background exposures (absent these background exposures, the NOEL of 0.007 mg/Kg-day would be expected to be higher).

Since the RfD is based on a NOEL versus the traditional NOAEL, EPA is already building in extra levels of protection. The current request for comments recognizes that this is a departure from the traditional approach and that the NOEL which is based on "using a nonadverse effect that is upstream of the adverse effect is a more conservative and health protective approach". The NRC's use of a precursor to an adverse effect is represented in Figure 1. The RfD represents a point of departure (POD) that precedes the inhibition of iodine uptake by the thyroid.

Figure 2 provides a generic representation of the difference between the NOEL and NOAEL. Given the very conservative and precautionary nature of the RfD, further adjustment of the RfD as suggested by the Agency for purposes of recommending HRLs is unwarranted. This is further supported by the epidemiological studies that cover multiple life stages at perchlorate levels above and below the suggested HRLs and observed no adverse effects.

Figure 1. Depiction of Point of Departure (POD) used to derive NOEL [see PDF docket ID EPA-HQ-OW-2009-0297-0415]

Figure 2. Perchlorate RfD represents a conservative point of departure (POD) for hazard assessment [see PDF docket ID EPA-HQ-OW-2009-0297-0415]

EPA Document ID: EPA-HQ-OW-2009-0297-0495
EPA Comment ID: 28862
EPA Comment Code: 5225

Comment: 4) MassDEP supports setting the HRL on the basis of the life stage(s) with highest exposure and risk with a 90% percentile ingestion rate, which is standard practice. Based on Table 2, this would support an HRL of 2 ppb (or perhaps somewhat lower depending on the exposure estimate for the 7-day old). It is worthwhile to note that the alternative HRLs calculated using the 95th percentile exposure values for early life stages are not very different than the HRL values estimated using the 90th percentile ingestion rates, especially considering the rounding involved in the final calculation of the HRLs. Although EPA's concern about sample size and aggregation of life stages is legitimate, the aggregation of life stages in the current document (birth to < 6 months) yield closely similar HRL values derived for life stages birth to < 1 month, 1 to < 3 months, and 3 < 6 months and birth < 6 months and therefore appear to be reasonably stable estimates (Table 2).

Response: See response to comment code 5220.

EPA Comment Code: 5225

Comment: 2. Derivation of alternative Health Reference Levels (HRLs) based upon body weight and water consumption rates for sensitive life stages: The alternative HRL calculation which relies on life-stage specific body weight and water consumption rates is not scientifically justified. Authoritative bodies (e.g., NRC, EPA, the Agency for Toxic Substances and Disease Registry, the California Environmental Protection Agency Office of Environmental Health Hazard Assessment (OEHHA)) have conducted rigorous scientific assessments and have determined that the fetus of the hypothyroid pregnant woman is the most sensitive to perchlorate's potential health effects, not the infant as suggested by the alternative HRL calculation. The Notice provides no scientific evidence that shows otherwise and offers no justification for basing a HRL on an alternative population that is not the most sensitive. Further, the values given in the Notice for specific exposure assumptions do not meet the Agency's own guidelines for data quality.

Response: See response to comment ID 28752 under comment code 5225 for a discussion of considering life stage specific exposure data in calculating HRLs.

Regarding the comment that the values given in the notice for specific exposure assumptions do not meet the Agency's own guidelines for data quality, see response to comment ID 28836 under comment code 5225.

Commenter Name:

Comment: II. RESPONSES TO REQUEST FOR COMMENTS ON ALTERNATIVE APPROACHES TO ANALYZING SCIENTIFIC DATA RELATED TO PERCHLORATE IN DRINKING WATER

Compared to the EPA PBPK model, the alternative HRLs listed in the Notice are not scientifically rigorous.

The Agency's process is not transparent in how it might use any of the three alternative approaches described in the Notice to revise its regulatory determination for perchlorate. For example, the Notice does not remark if it intends to use both the PBPK model and the HRL "model." Further, the Notice is not clear about how the Agency intends to integrate the results of these alternative approaches with existing knowledge about the threshold for IUI in average adults.

The comments in this document assume EPA does not intend to apply both the PBPK model and alternative HRLs based on body weight and water consumption. Further, this document assumes that EPA seeks input on whether one approach is scientifically more accurate than the other for extrapolating from a no effect dose measured in adults to sensitive subpopulations. Overall, the scientific community supports the use of PBPK modeling when all parameters are based on scientific experiments (Mager et al., 2003). When scientifically validated, PBPK models can be useful to reduce uncertainty about sensitive life stages. In contrast and as will be discussed below, the HRLs based on body weights and water consumption rates do not reflect a similar scientific basis.

It is important to note the difference between the results in Table 1 of the Notice (which presents the PBPK model-predicted RAIU inhibition for each life stage) and Table 2 (which presents the alternative HRLs based on body weight and water consumption). The RAIU inhibition estimates in Table 1 were computed using a dose of 0.007 mg/kg-d, the Greer et al. (2002) POD. This dose is equivalent to 245 ppb of perchlorate in drinking water if one uses standard EPA default values for body weight and drinking water consumption.[FN7: 0.007 mg/kg-d x (70 kg adult / drinking 2 L of water per day = 0.245 mg/L or 0.245 ppm or 245 ppb.] The HRLs in Table 2 are based on the perchlorate RfD which is ten times lower, i.e., 0.0007 mg/kg-d or 24.5 ppb. Therefore, anyone comparing Tables 1 and 2 should recognize a 10-fold difference in the underlying dose assumptions. For example, the highest RAIU inhibition reported in Table 1 is 12.5% for the lactating woman and breast-fed infant exposed to a dose of 0.007 mg/kg-d. At the 10-fold lower RfD in Table 2, the RAIU inhibition for the lactating woman and breast-fed infant would be approximately 2%, a value

that would not be significantly different from normal fluctuations because of differences in diet and feeding styles. There is no credible scientific evidence that this effect has any biological significance.

Based on the EPA PBPK model, at the RfD, the RAIU inhibition for the exclusively breast-fed infant would be approximately 2%, a value that would not be significantly different from normal fluctuations due to diet.

Response: EPA was transparent in our August 2009 discussion of how we might consider the alternative HRLs in lieu of the single HRL of 15 ug/L used for the October 2008 notice. The agency was also clear that we were reconsidering our application of the PBPK model in light of how the comments we had received from both our peer reviewers and the commentors on the notice. See response to comment ID 28923 under comment code 2400 for a discussion of our decision not to use the PBPK modeling to inform the final regulatory determination.

EPA Comment Code: 5225

Comment: B. Derivation of Alternative HRLs Based on Body Weight and Water Consumption Rates for Sensitive Life Stases

The NRC panel and subsequent studies consistently identify the fetus as the most sensitive population for perchlorate health effects evaluation.

In October 2008, EPA calculated an HRL for perchlorate in drinking water based on the RfD and a RSC of 62%, and EPA's default body weight and water consumption rates for an adult (U.S. EPA, 2008a). Based on a comment regarding the adequacy of EPA's proposed HRL to be protective of sensitive life stages, EPA presented an alternative calculation of an HRL in the Notice based on weight-normalized water intakes for specific life stages.[FN13: For example, EPA says, "One commenter cites a March 8, 2006, letter from the Children's Health Protection Advisory Committee to the EPA Administrator. The commenter states, "[T]he committee emphasized the higher exposure of infants to perchlorate and greater susceptibility to serious negative effects associated with perchlorate exposure. Neither of these issues, however, was given adequate consideration in the Preliminary Determination."] EPA has not presented any scientific evidence for why its proposed HRL in October 2008 was inadequate to protect other life stages or why it would be necessary to add additional safety factors to the RfD in the form of life stage-specific intake rates. In contrast to the PBPK model, the alternative HRL approach:

* is based primarily on one variable (the water intake rate);

* uses data that are not derived from scientific experiments but from a summary obtained in a survey that relies on subject recall rather than direct measurement;

* relies on methods that are incapable of measuring, estimating, or predicting the effects of a chemical on the body; and

* produces results that are qualitative at best.

In summary, determining the most sensitive life stages based on water consumption rates implicitly makes general assumptions about numerous body functions in lieu of actual scientific data about physiological differences between these population groups. This "model" does not account for absorption, distribution, or excretion, regardless of the individual's state of development. It implicitly assumes that the potential for exposure is directly proportional to body weight, without scientific supporting data.

PBPK modeling provides a more scientifically defensible approach to characterize the relative sensitivity of different life stages to perchlorate exposure. The Notice's alternative HRL calculations are insensitive, duplicative, and not scientifically warranted.

The Notice should be transparent that the alternative HRL calculation it presents is an arithmetic calculation based on only three variables: the RfD, an RSC, and life stage specific water intake rates. Of these, the only scientifically defensible value is that upon which the RfD is based- the POD derived from Greer et al. (2002). The RSC is based on the mean intake of perchlorate from the Food and Drug Administration (FDA) Total Diet Study for the nearest age range, and the 90th percentile intake from a NHANES-UCMR analysis for pregnant women and women ages 15-44 that was conducted for preliminary regulatory determination. Using the 90th percentile is a not a science-driven decision. The water intake by body weight is arbitrarily categorized by age (i.e., what is physiologically unique about 6 months of age versus 5 months of age?). Further, the consumption values for the infant are based on a study in which the study participant had to recall their own (or their infant's) consumption over two non-consecutive days; no direct measurements were taken. Recall studies are subject to error (called recall bias) from lapses in memory on estimations of amounts consumed (i.e., what, when, and how much did I eat or drink?). In addition, the population size in this study does not meet EPA's data quality standards.

The EPA has asked for comment on four general questions regarding the Notice's alternative HRL calculations. Responses to these questions, based on the best available scientific information, follow.

1. EPA requests comment on whether the alternative HRLs described in this notice appropriately take into account specific and appropriate exposure values for all potentially sensitive life stages, including infants, children and the fetuses of pregnant women (rather than the 70 kg body weight and 2 liter per day consumption used for past regulatory determinations).

The HRL methodology that the Notice describes does not appropriately account for sensitive life stages for several reasons: (1) the most sensitive population has already been considered in the perchlorate RfD; (2) EPA provides no scientific justification for why this alternative HRL is necessary; and (3) there are no scientific data that meet EPA data quality requirements to substantiate the calculations used to develop these HRLs.

Response: The NRC (2005) identified "the fetuses of pregnant women who might have hypothyroidism or iodide deficiency" as "the most sensitive population," but also identified infants and developing children as additional "sensitive populations." Infants and young children have greater exposure to contaminants in food and water because of greater consumption of food and water on a per unit body weight basis. Therefore, these life stages may be the most vulnerable populations when their relative exposure is considered. Therefore, EPA used this approach to derive

HRLs by evaluating exposures at different life stages. See response to comment ID 28752 under comment code 5225 for more discussion.

EPA believes that data to evaluate drinking water consumption on a per body weight basis are critical for comparison to the RfD for perchlorate. EPA further believes that the exposure data used by the Agency are the best available peer reviewed data.

EPA Comment Code: 5225

Comment: The historic standard procedure for converting the RfD into drinking water equivalent levels (DWELs) assumes 2 liters (67.6 oz) per day of water consumption and a body weight of 70 kg (154 lbs). One important purpose of converting the RfD (in units of mg/kg-day) to a DWEL (in units of ug/L or ppb) is to make it easy to compare water concentrations of contaminants to government guidelines. In doing so, EPA conservatively opts for higher than average intake and lower than average body weight. Thus, these default values are not symmetrically representative of the population. The water consumption (2 liters) default is approximately equal to the 88th percentile water intake for adults aged 20 through 64 (U.S. EPA, 1997). The default body weight of 70 kg is approximately equal to the 27th percentile of the distribution for adult males aged 18-74 and the 70th percentile of the distribution for adult females (U.S. EPA, 1997). Because the conversion uses the ratio of body weight to water intake, the use of lower percentiles in the numerator than are used in the denominator leads to a biased overestimate of the dose.

The DWEL is based on the RfD. The RfD is defined as (NRC, 2005):

...an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without risk of deleterious effects during a lifetime. It can be derived from a NOAEL, LOAEL, or BMD, with UFs generally applied to reflect limitations of the data used.

Therefore, by definition, the RfD already accounts for the most sensitive population and lifetime exposures. In the most recent review of the RfD process, the EPA technical committee recommended (U.S. EPA, 2002):

The intraspecies UF is applied to account for variations in susceptibility within the human population (interhuman variability) and the possibility (given a lack of relevant data) that the database available is not representative of the dose/exposure-response relationship in the subgroups of the human population that are most sensitive to the health hazards of the chemical being assessed. As the reference concentration/dose is defined to be applicable to "susceptible subgroups," this UF was established to account for uncertainty in that regard.

EPA remarks that additional factors should not be applied to determine a MCLG. For example, in the Disinfectant and Disinfection Byproduct rule (enacted during the Clinton Administration), EPA rejected additional safety factors for children or adjusting the default adult body-weight/consumption parameters:

EPA disagrees that an additional safety factor should be applied to provide additional protection for children or that drinking water consumption relative to body weight of children should be used in developing the MCLG (maximum contaminant limit goal). The MCLG presented for chlorite and chlorine dioxide are considered to be protective of susceptible groups, including children, given that the RfD is based on a NOAEL derived from developmental testing. Additionally, current methods for developing RfDs are designed to be protective for sensitive populations. The 2 liter per day water consumption and the 70 kg body weight assumptions are viewed as adequately protective of all groups (U.S. EPA, 1998b).

Lifetime exposure includes exposure during infancy. An RfD that failed to account for exposure during infancy would fail to satisfy the standard definition. Applying life stage specific drinking water values would, in effect, "double count" the UF that has already been applied.

EPA requests comment on the alternative HRLs in Table 2 and which of these values would be appropriate levels of health concern against which to compare the levels of perchlorate found in public water systems.

The calculated values presented in Table 2 are not scientifically justified. Although this table presents levels that have been found in public water systems, there is no health effect associated with the values presented. In fact, every life stage calculation in Table 2 corresponds to a no effect level, based on IUI which is a fully reversible, nonadverse effect that occurs on a routine and daily basis.

The NRC noted that the dose at which perchlorate might cause hypothyroidism is greater than 0.4 mg/kg-d (14,000 ppb using default drinking water and body weight conversions). It states (NRC, 2005):

On the basis of the studies of long-term treatment of hyperthyroidism in which patients continued to be given perchlorate after their hyperthyroidism resolved and the clinical studies of healthy adults, the perchlorate dose required to cause hypothyroidism in adults would probably be more than 0.40 mg/kg per day, assuming a 70-kg body weight.

Importantly, the NRC (2005) also emphasizes:

The committee emphasizes that inhibition of iodide uptake by the thyroid has been the only consistently documented effect of perchlorate exposure in humans. The continuum of possible effects of iodide-uptake inhibition caused by perchlorate exposure is only proposed and has not been demonstrated in humans exposed to perchlorate (with the exception that in patients with hyperthyroidism doses of 200 mg daily or higher may reduce thyroid secretion).

The PBPK results, as presented in Table 1 of the Notice, show the 1 week old breastfeeding infant to have the greatest RAIU inhibition when its mother is given a dose 10 times greater than the RfD (e.g., exposure at water concentration of 245 ppb). This assumes that the infant would be exclusively breastfed. In calculating the HRL, the age groups that had the greatest intake per body weight, however, were the youngest infants who are exclusively formula fed. Based on the PBPK model, the bottle fed infant had a 1.5% change in RAIU inhibition, which is well within the normal variation of RAIU inhibition.

2. EPA requests comment on whether EPA used the best available and most appropriate data to estimate alternative HRLs in Table 2 (denoted by footnote c) where the sample size does not meet the minimum data requirements as described in the "Third Report on Nutrition Monitoring in the United States" (LSRO, 1995). Does aggregating life stages (birth to 6 months, and women ages 15-44) address sample size limitation and still provide an accurate representation of the exposure to the most vulnerable life stages?

The drinking water intake rates in the age groups are based on USDA Continuing Study of Food Intakes by Individuals from 1994-1996 and 1998. This was a large study of dietary recall and was reported by Kahn and Stralka (2008). Although this may be the best study that the Agency could find, it is neither sufficient nor does it meet the scientific standards the EPA's own guidelines demand for a regulatory process.

First, compared to the science-based data used in a PBPK model, water intake is an insensitive variable. It cannot be used for measuring, estimating, or predicting the effects of a chemical on the body. In fact, it does not and cannot estimate or predict any effects in the body. This study is not based on a specific experiment, but a summary of data obtained in a survey based on recall rather than direct measurements. The best and most scientific process would be to measure and record the exact amount of fluid or food intake at the time of ingestion.

Second, as noted by EPA in the Notice, for some life stages, the data do not meet EPA guidelines on data quality.[FN14: The Notice states "The sample sizes for the estimates of ingestion rates for these life stages do not meet the minimum data requirements as described in the "Third Report on Nutrition Monitoring in the United States" (LSRO, 1995)."] Water intake as the sole variable makes general assumptions about numerous body functions in lieu of actual data. For example, in effect, this calculation does not account for absorption, distribution, or excretion, regardless of developmental state. This calculation implicitly assumes that the body's disposition of perchlorate is directly proportional to body weight. There are no scientific data to support these assumptions.

Third, the study population in Kahn and Stralka (2008) may not be representative of the U.S. population. The body weights presented by Kahn and Stralka (2008) are lower than that found in 1996-2000 NHANES data, as presented by EPA in the Child Specific Exposure Factors Handbook (U.S. EPA, 2008d) and may not be representative of the general population. For one month olds, the Kahn and Stralka (2008) mean, 90th and 95th percentile body weights are 20, 45, and 24% lower than the NHANES 1996-2000 data. A greater body weight will result in a lower total dose, if intake is the same. The comparison body weights for the three youngest age groups are presented in Table 1 in Appendix A.

Fourth, Kahn and Stralka (2008) is a recall study. As noted above, this is a study in which the study participant had to recall their own (or their infant's) consumption over two non-consecutive days. No direct measurements were taken. Recall studies are subject to bias from errors in memory when recalling the amounts consumed (i.e., what, when, and how much did I eat or drink?). For example, it is possible and not unusual that the person reporting the infant intake estimated a high value for intake. If this occurred for one or two individuals in the study, the data would be skewed (as observed by inspection), overestimating the statistical estimation of the 90th and 95th percentile water consumption values.

Applying life stage specific drinking water values is, in effect, "double counting" the uncertainty factor that has already been applied.

Furthermore, a dietary recall study should represent the entire population, not just tap water consumers. The water intake from Kahn and Stralka (2008) were calculated based on individual parameters. EPA chose to use the data for consumers of water only, yet individuals commonly use water from other sources (e.g., bottled, in juice or soda). Since the EPA is interested in developing a MCL, sources of water that would be regulated are municipal water systems. One effect of choosing not to use the analysis of all individuals is that the results are higher than what would be reflected if all data were used. That is to say, this would not be a science-based decision. The results of using ingestion rates from consumer versus all individuals on the alternative HRLs are presented in Table 2 in Appendix A. To illustrate the effect noted above of limiting the population, in infants less than one month of age, the proposed alternative HAL based on consumers only was 3 ug/L; if the value for all individuals is used, the water concentration would be 8 ug/L.

EPA reports intake rates and alternative HRLs based on the mean, 90th, and 95th percentiles. Kahn and Stralka (2008) lack sufficient study size and methodology to reliably inform the science related to the general population, as the Notice acknowledges.

One way to gauge whether the 90th and 95th percentile values suggested in the Notice are statistically unreliable is a simple comparison to blood volume. The average adult has a blood volume of approximately 5 L and drinks approximately 1.4 L/d, or 27% of their blood volume (U.S. EPA, 1997). It is well understood that infants and children consume more than adults when normalized for body weight, but using the intake rates suggested by EPA, the 95th percentile one month old infant would consume 2.6 L/d or 280% of their blood volume. This is the equivalent of the average adult consuming just under 4 gallons, every day. Comparisons of water intake to blood volume are presented in Appendix A, Table 3.

The RfD is based on the study by Greer et al. (2002) and the researchers in this study did not control dietary intake of perchlorate or other natural agents such as nitrate, thiocyanate, or iodine. Perchlorate has been detected in many foods, including but not limited to milk, lettuce, and cantaloupe (Murray et al., 2008). No perchlorate was reported detected in Portland's city water supply (the location of the study) according to UCMR1. Thus, assuming that Murray et al, (2008), is correct, subjects would have received perchlorate from food (See Figure 1). Therefore, the dose of perchlorate that resulted in a NOEL was in addition to the background level of perchlorate ingested through food. If the background dose of perchlorate from all sources was 0.02 to 0.234 ug/kg-d (the 5th and 95th percentile estimated doses from Blount et al. (2007)), then all doses in Greer et al. (2002) underestimate the true dose by this amount and the RSC has already been considered.

Figure 1. Visual representation of UF, the RfD, and unaccounted for contribution of perchlorate in food are components of the POD dose. [see PDF docket ID EPA- HQ-OW-2009-0297-0662]

3. EPA requests comment on the merits of the approach described here of deriving HRLs for sensitive life stages based on the RfD combined with the life stage specific exposure data and whether there are other approaches that may be useful for deriving HRLs.

Given the strength of the underlying science in the EPA PBPK model, the proposed HRLs in the Notice do not address sensitive life stages in a scientifically justified manner.

Some have suggested that perchlorate should be regulated differently because its acute effects may be detrimental during sensitive life stages. This assumes that the UF applied to the RfD is not large enough to account for the most sensitive life stage. Such a claim would be not supported by scientific evidence. First, toxicologically speaking, an acute effect is an effect seen after one high dose or an exposure of less than 24 hours. No published study has demonstrated an effect after one exposure to perchlorate at environmental levels. Even if acute is meant to refer to effects over several weeks to months (more commonly termed "subchronic") of exposure, no study demonstrates adverse effects at environmental levels, nor would an effect be expected based on the current scientific literature. As the Greer et al. (2002) study demonstrated, any IUI at the POD dose is within normal variation and there is no evidence that any effects, much less any adverse effects, would be expected at doses near the RfD, on a short-term or chronic (lifetime) basis.

Response: See response to comment ID 28752 under comment code 5225 for a discussion of the use of life stage specific exposure values for determining HRLs. See response to comment code 5210 for a discussion of the relative source contribution. See response to comment ID 28338 under comment code 5225 for a discussion of the health implications of exposure above the RfD.

Comment: 2. The proposed use of alternative HRLs based upon body weight and water consumption of other life stages is not a scientifically-based process. If there were a lack of data for a particular chemical, then perhaps this approach would be defensible. For perchlorate, however, where the effort of scientists to reduce uncertainty has been long standing and focused, the use of body weight and water consumption would increase uncertainty. The PBPK modeling provides greater and more biologically significant information.

Response: See response to comment ID 20432 under comment code 5220 for a discussion of EPA's decision regarding the use of the PBPK model in the regulatory determination.

Comment: Alternative HRLs Based Upon Body Weight and Water Consumption of Other Life Stages

In the October 10, 2008 notice, the proposed Health Reference Level (HRL) for perchlorate of 15 ug/L was derived using exposure assumptions for a pregnant woman/fetus exposed to the RfD of 0.7 ug/kg/day with a Relative Source Contribution (RSC) factor of 0.6. In developing this HRL, USEPA assumed that the fetus is the most sensitive subpopulation, more sensitive than the infant, so that the infant could be safely exposed to much higher doses than the fetus.

We strongly disagree with the assumption that exposure of infants to perchlorate above the Reference Dose is acceptable. We urge USEPA to use exposure assumptions for all potentially sensitive life stages, especially infants and children, to derive alternative HRLs that are protective of all sensitive subgroups. A similar approach that considers exposure assumptions for infants was used by the NJDWQI (2005) in developing its recommendation for a perchlorate MCL, and by NJDEP (2009) in developing its MCL proposal. We strongly support USEPA's approach based on combining the RfD, which is intended to protect sensitive subpopulations, with exposure data specific for sensitive life stages such as infants. We do not advocate other approaches for deriving HRLs.

Comment: 2) Alternative Health Reference Levels (page 41889)

ACWA has reviewed the table referenced in the request for comments and we believe that an educated answer is not feasible as the various levels are not based on science connecting exposure to any actual observed adverse health effect. We encourage USEPA to seek out or initiate studies that may better inform such a significant dataset.

EPA Document ID: EPA-HQ-OW-2009-0297-0499
EPA Comment ID: 28929
EPA Comment Code: 5225

Comment: On August 19, the agency published a notice in the Federal Register seeking comments on its additional approaches to analyzing data related to its perchlorate regulatory determination. These new approaches differ from EPA's prior assessment primarily because they focus on the risks of perchlorate exposure to infants and children, as opposed to the prior assessment that focused on risks to the fetus of the hypothyroid or iodide-deficient woman. EWG fully supports these approaches. Although fetal development is a highly vulnerable life stage for perchlorate exposure, research from the last several years has confirmed that infants and children are an equally high-risk population group due to their small size relative to adults and their high level of perchlorate exposure via water and food.

Response: See response to comment code 5220.

Commenter Name: Anila Jacob
Commenter Organization: Environmental Working Group (EWG)

EPA Document ID: EPA-HQ-OW-2009-0297-0499
EPA Comment ID: 28931
EPA Comment Code: 5225

Comment: Appropriateness of alternative HRLs: EWG supports the alternative HRLs if they are modified to reflect risks to infants from widespread perchlorate contamination of powdered infant formula and if infants under six months of age are not aggregated in the agency's exposure assessment.

Further in its assessment, the agency also lists a number of new Health Reference Levels (HRLs) as an alternative to its proposed HRL of 15 ppb from December, 2008. The agency derived these new HRLs by evaluating exposure to perchlorate at different life stages. In Table 2 of the notice, the Agency lists HRLs for 14 different life stages at three different drinking water ingestion rates (average, 90th, and 95th percentile).

Ten of the life stages are for children 16 years old or younger, indicating the Agency's recognition that perchlorate exposures vary during each stage of childhood.

For drinking water ingestion rates at the 90th and 95th percentile rates for infants in the three youngest life stages, the Agency notes that the sample sizes for the estimates of ingestion rates do not meet established minimum data requirements. The actual sample sizes for these three groups are 37 (birth to <1 month), 108 (1 to < 3 months), and 269 (3 to <6 months). While they may not meet minimum data requirements, EWG strongly supports their use because these are the best data available (EPA 2008), and because aggregating these age groups masks significant exposure disparities in these critical life stages.

Infants in the youngest two life stages (birth to <1month and 1 to <3 months) have especially high drinking water ingestion rates. HRLs derived from the aggregated life stage of birth to <6 months would place some of the very young infants at high risk of exceeding the current RfD. For example, the HRL for the aggregated life stage at the mean ingestion rate is 4 ug/L. This would leave infants under three months of age at high risk of exceeding the RfD because they require an HRL of 3 or less to limit cumulative exposure below the RfD.

The HRLs are lowest for children ages two and under, consistent with the published data showing that infants and children have high baseline perchlorate exposures from food and relatively high water ingestion rates; therefore, infants and young children can easily exceed the current RfD by drinking tap water contaminated with even very small concentrations of perchlorate (Murray et al 2008, EWG 2008). For infants six months of age and under, the agency estimates HRLs from 1 to 5 parts per billion, depending on the exact age and mean drinking water ingestion rate.

Commenter Organization: Massachusetts Department of Environmental Protection (MassDEP)
EPA Document ID: EPA-HQ-OW-2009-0297-0495
EPA Comment ID: 29098
EPA Comment Code: 5225

Comment: 3) Other sensitive populations should not be forgotten when EPA is addressing levels of health concern and potential numbers of people exposed to perchlorate in drinking water. Other sensitive subgroups not explicitly addressed include individuals with low iodine intake, untreated thyroid conditions, those suffering from cardiovascular and renal diseases (Miller et al. 2009; Iglesias and Diez 2009), individuals exposed to mixtures of other thyroid stressors, the elderly who are often prone to thyroid problems, and people with thyroid cancer. The results of Blount et al 2006 also indicate that women should be considered a sensitive group, certainly at the current RfD.

Response: EPA has calculated HRLs for women ages 15-44 as part of the final regulatory determination.

EPA agrees that these are sensitive groups and will consider them during the rulemaking process.

EPA Comment Code: 5230 Calculation of frequency of exposure above the HRL among pregnant women

Individual Comments
Commenter Name: Gregg Grunenfelder

EPA Document ID: EPA-HQ-OW-2008-0692-1529
EPA Comment ID: 20457
EPA Comment Code: 5230

Comment: Table 2 presents a subset of EPA developed estimates of the population served by water systems for which the highest reported perchlorate concentration was greater than various threshold concentrations ranging from 4 ug/L to 25 ug/L. If lower threshold values derived from California, New Jersey, or Massachusetts were applied, the estimated number of potential exposed population would greatly increase. No value was estimated for a threshold corresponding to Massachusetts MCL of 2 ug/L, but is likely to be doubled that projected for a threshold value of 4 ug/L with greater than 30 million people within the United States potentially served by Public Water Systems with at least one detection greater than the threshold. The population estimates for entry or sample points having at least one detection greater than the threshold would likely be over 10 million, half of whom are female and greater than 210,000 may be pregnant at anyone time.

EPA Comment Code: 5230

Comment: IV (B)(4), p 60277. The calculation of frequency of exposure makes the argument that a small proportion of women is pregnant at any one time, and therefore the percentage of the population at risk is quite limited, and there is no meaningful opportunity for a health risk reduction. This calculation ignores the fact that every individual is born of a pregnant female, and therefore the entire population of exposed individuals can be at risk at a critical formative period. The logical flaw in the EPA argument was to count pregnant females as at risk, rather than their fetuses, which assumes the effect is transient (in the pregnant females) rather than potentially permanent (in their offspring).

EPA Document ID: EPA-HQ-OW-2008-0692-1432
EPA Comment ID: 20916
EPA Comment Code: 5230

Comment: However, even with the many errors, flaws, and omissions in EPA's assessment, EPA still estimates that up to 2 million people throughout the U.S. could potentially be consuming water with levels of perchlorate that exceed this HRL. Here is EPA's exact statement:

"EPA's best estimate is that 0.9 million people (with an upper bound estimate of 2 million people) may be consuming water containing perchlorate at levels that could exceed the HRL for perchlorate and the Agency estimates that fewer than 30,000 of them are pregnant women at any given time" (EPA 2008).

It is astounding that EPA does not think it is necessary to set a stringent drinking water standard for perchlorate in order to protect 30,000 pregnancies annually. In addition, the 2 million people at risk include infants and children, so the subpopulations within this number that would benefit from a stringent drinking water standard would far exceed 30,000.

EPA Comment Code: 5230

Comment: VIII. EPA Should Publish a More Accurate Estimate of the Population Exposed above the HRL in the Final Determination

In the proposed determination, EPA estimates that 16,000 pregnant women may consume drinking water with concentrations above the HRL of 15 ppb. It was appropriate to estimate pregnant women, because although we all begin life as a fetus, the fetal exposure period is finite and an individual becomes less susceptible to the effects of possible reduced thyroid function as he ages. The actual number is likely to be much lower than the estimate in the proposed determination.

Response: Please see response to comment code 5220.

EPA Document ID: EPA-HQ-OW-2008-0692-0962
EPA Comment ID: 20419
EPA Comment Code: 5240

Comment: A number of states have recently established perchlorate drinking water standards or goals that are more appropriate than USEPA's HRL published in the Oct 10th FR notice. The New Jersey MCL is 5 ug/L, the California Public Health Goal is 6 ug/L and the Massachusetts MCL is 2 ug/L. These drinking water values were intended to keep perchlorate exposures below the RfD for all groups including young children. Approximately 4% of public water supplies serving 17 million Americans would be in exci.edance of an HRL between 2 and 6 ug/L. This is 15 million more at risk individuals than currently estimated by the Agency. Thus, the proposed HRL of 15 ug/L has the potential to leave large numbers of infants inadequately protected against perchlorate.

Response: EPA has determined that perchlorate meets the criteria for regulating a contaminant in Section 1412(b)(1)(A) of SDWA. When EPA proposes the NPDWR for perchlorate, the Agency will also propose a Maximum Contaminant Level Goal (MCLG) for perchlorate. See response to comment code 5220.

EPA Comment Code: 5240

Comment: Perchlorate interferes with thyroid function in both animals and humans. A consideration of known differences in thyroid physiology between adults and neonates/infants supports the conclusion that the neonate and infant are the most "at risk" population.

Three important differences in thyroid physiology between adults and neonates/infants supports the conclusion that this population is the most vulnerable to perchlorate exposure (reviewed by (Ginsberg et al., 2007)):

1) Serum half-life of the thyroid hormone T4 is substantially longer in the adult relative to the neonate (7-10 days (Chopra and Sabatino, 2000)) versus 3 days (Lewander et al., 1989; van den Hove et al., 1999). This means that for adults, serum thyroid hormone levels are stable in the face of the daily fluctuations in perchlorate exposure and iodine uptake that might arise from drinking water contaminated with perchlorate. In contrast, the shorter serum half-life of T4 in the neonate means that there will be a much more rapid response to the inhibition of iodine uptake by perchlorate.

2) The adult thyroid gland stores a considerable amount of hormone, possibly enough for several months of normal secretion (Greer et al., 2002). Consequently, adults can presumably function normally without new hormone synthesis for extended periods. In contrast, the neonatal thyroid gland contains essentially no extra hormone and the amount of thyroid hormone in the neonatal gland represents a single day's worth of hormone (van den Hove et al., 1999). Therefore, the neonate must generate new hormone on a daily basis and perturbations in iodine uptake can have significant consequences.

3) The adult thyroid system can compensate for low thyroid hormone levels and the consequences of low thyroid hormone are likely to be reversible. This is in contrast to the neonatal thyroid gland which does not readily compensate for low thyroid hormone (reviewed by (Ginsberg et al., 2007)), and the consequences of low thyroid hormone at this time are not reversible (reviewed by (Rovet, 2002; Zoeller and Rovet, 2004).

Thus, neonates and infants represent unique "at risk" populations in the matter of perchlorate exposure and its effects on public health.

Comment: Considering that the Blount study (Blount et al., 2006a) is the only study available to the EPA that had the ability to identify a relationship between life-time, low-dose perchlorate exposure and thyroid function, this study should supercede the Greer 2002 study for the derivation of the RfD. This study demonstrates that, in women with low urinary iodide, perchlorate exposure at the 50th percentile is associated with a 1.06 ug/dL reduction in serum total T4. While this may be of uncertain clinical significance to adult women, it is clinically significant to an infant during highly sensitive periods of postnatal brain development. In addition, the EPA would then be in a stronger position because it would be regulating on hormone reduction, rather than iodide uptake inhibition. Moreover, it is now conclusively shown that perchlorate is transported by the sodium/iodide symporter (NIS) (Dohan et al., 2007) and is found at high levels in human milk (Kirk et al., 2007; Pearce et al., 2007). Thus, the US EPA should recalculate the RfD and HRL based on the CDC study as the point of departure.

US Environmental Protection Agency Office of Water Docket (Mail Code: 2822T) 1200 Pennsylvania Avenue, NW Washington, DC 20460

Ref: Docket EPA-HQ-OW-2008-068

Dear Sirs/Mmes:

In the October 10, 2008 Federal Register EPA made a preliminary determination that not enough people in the United States are exposed to significant levels of perchlorate in public drinking water systems to merit the issuance a national primary drinking water regulation. This is one of the most disappointing and convoluted EPA documents that I have ever reviewed.

To reach that conclusion, it proposes to specify a health reference level of 15 parts per billion (ppb) based on its current reference dose of .7 micrograms per kilogram per day and a calculation of dietary sources of perchlorate other than drinking water. As other commenters have explained, EPA has failed to recognize that this health reference level exposes young children to levels of perchlorate above the reference dose.

Response: See response to comment code 5220.

EPA Comment Code: 5240

Comment: Many experts disagree with your assessment that drinking water with 15 parts per billion of perchlorate is safe and acceptable. Scientists from the California Environmental Protection Agency and the Massachusetts Department of Environmental Protection have set stricter standards to will ensure that the most vulnerable populations -- pregnant women, infants, and small children -- are protected from the adverse impacts of perchlorate.

Response: See response to comment code 5220.

EPA Comment ID: 20913
EPA Comment Code: 5240

Comment: EPA focuses on risks to pregnant women while ignoring evidence of risks to breastfed infants and young children: There have been at least four published studies that highlight widespread perchlorate contamination of human breast milk. The most recent of these also postulated that perchlorate is preferentially excreted into breast milk when compared with iodine. Just as troubling, the average levels of perchlorate in breast milk in these studies would expose a significant number of breast fed infants to perchlorate levels above EPA RfD of 0.7 ug/kg/day. Breast fed infants do not get thyroid hormones through breast milk and must produce these hormones themselves; they are completely dependent on maternal iodine for thyroid hormone production and perchlorate exposure through breast milk could significantly inhibit this process. Adequate levels of thyroid hormones during infancy are integral to normal growth and brain development.

Yet, despite growing evidence that breast fed infants are one of the most highly exposed populations and are uniquely vulnerable to perchlorate, EPA chooses to ignore this data. EPA does not even acknowledge this population as being at risk. In fact, EPA notes that "The subpopulation that is the most sensitive to perchlorate exposure is the fetus of the iodine-deficient pregnant women" while ignoring the evidence of risks to infants (EPA 2008).

Similarly, young children are also highly exposed to perchlorate; FDA found that perchlorate contaminates 74% of 300 commonly consumed foods and beverages (Murray et al. 2008). It is well established that children eat and drink more, pound for pound, than adults. For this reason, perchlorate contamination of food is especially concerning for young children. FDA finds that among 2 year olds, perchlorate exposures from contaminated food and beverages alone fall between 50 and 56% of EPA RfD of 0.7 ug/kg/day (Murray et al. 2008). EWG analysis of FDA data finds that additional exposures to perchlorate from contaminated drinking water could easily result in combined exposures that exceed the EPA RfD. The average two year old will exceed EPA's RfD for perchlorate by drinking water that is contaminated with as little as 4 ppb of perchlorate (EWG 2008).

EPA does not explore risks to young children in any detail in their assessment, despite clear evidence from FDA research that perchlorate exposures from food are higher for young children than any other demographic group. As mentioned earlier, EPA focuses on the developing fetus of iodine-deficient pregnant women as the subpopulation that is at highest risk from perchlorate exposure while explicitly ignoring evidence that breast-fed infants and young children are also at risk.

Response: EPA believes the NRC appropriately based the RfD on iodide uptake inhibition to the thyroid, for the reasons discussed in its report. See response to comment ID 28927 under comment code 2110.

EPA Comment ID: 20926
EPA Comment Code: 5240

Comment: Concern raised by the Children's Health Advisory Committee regarding the unique levels of exposure and developmental impacts of perchlorate on breast-fed infants were not addressed, and the reference dose[FN1: 0.7 ug/kg/day, or 49 ug/day for an adult weighing 70kg] upon which the EPA based the preliminary decision may not adequately protect the health of breast-fed infants. While the health risk posed by perchlorate to fetuses of pregnant women with hypothyroidism was considered in the preliminary regulatory determination, we are concerned that the health risk to breast-fed infants was not adequately addressed. Recommendations provided by the Children's Health Protection Advisory Committee (CHPAC) in its March 8, 2006 letter have not been appropriately adopted,[FN2: Children's Health Protection Advisory Committee. (2006, March 8). Letter to Stephen L. Johnson, EPA Administrator. Accessed Oct. 28, 2008 from http://www.ewg.org/files/chpac-epa_ltr.pdf.] which is especially disconcerting in light of the U.S. Government Accountability Office's (GAO) recent finding that the EPA has routinely failed to respond to this committee's findings.[FN3: U.S. Government Accountability Office (GAO). (2008). Environmental Health: EPA Efforts to Address Children's Health Issues Need Greater Focus, Direction, and Top-level Commitment. Accessed November 4, 2008 from http://www.gao.gov/new.items/d081155t.pdf.] Despite the EPA's recognition that children may be more vulnerable to environmental hazards, the GAO found that the EPA has failed to proactively seek advice from the CHPAC and "largely disregarded key recommendations" from the committee.[FN4: GAO. (2008). Environmental Health: EPA Efforts to Address Children's Health Issues Need Greater Focus, Direction, and Top Level Commitment. Retrieved Oct 27, 2008 from http://www.gao.gov/new.items/d081155t.pdf.] In the case of perchlorate, the committee emphasized the higher exposure of infants to perchlorate and greater susceptibility to serious negative effects associated with perchlorate exposure. Neither of these issues, however, was given adequate consideration in the Preliminary Determination.

* Perchlorate is actively transported into human breast milk where it concentrates, resulting in exposure levels above the reference dose for infants feeding on this milk. In the Preliminary Determination for perchlorate, the EPA used a reference dose designed to "estimate the daily oral dose that is likely to have no appreciable risk of deleterious effects during a lifetime"[FN5: National Research Council (NRC). (2005). Health Implications of Perchlorate Ingestion. Washington, D.C.: The National Academies Press, 208.] of 0.7 ug/kg/day. However, the CHPAC calculated that infants would be exposed to perchlorate levels approximately 5-10 times higher than this reference dose with a maternal exposure of 24.5 ug/L of perchlorate in water, plus a dietary intake of 8.4 ug/day. Because maternal exposure in this calculation is above the EPA's reference dose, we recalculated infant exposure with a total maternal perchlorate exposure equal to the reference dose (0.7 ug/kg/day). The results showed that a breast-fed infant would be exposed to approximately 5-8 times the reference dose.[FN6: Calculation of infant exposure to perchlorate: Nursing Infant Dose (ug/kg/d) = (ug/L in human milk/ug perchlorate ingestion-day) *[(24.5 ug perchlorate/L water)* (L water ingested/day)+ (baseline US dietary ingestion rate, ug/d)]*(L human milk ingested/day/infant body weight) Modified formula used by us to estimate infant exposure, with total maternal exposure equal to EPA's reference dose of 0.7 ug/kg/day (assuming adult body weight of 70 kilograms, as was used by EPA in the Preliminary Regulatory Determination): Maternal exposure: (0.7 ug/kg/day)*(70kg)= 49 ug/day Nursing Infant Dose (ug/kg/d) = (ug/L in human milk/ug perchlorate ingestion-day)*(49 ug/day)*(L human milk ingested/day/infant body weight) Aside from the maternal daily perchlorate exposure, we used the same parameter values as were used by the CHPAC. Please see the letter from CHPAC of March 8, 2006 for an explanation of these parameter values. Our infant exposure calculations: (0.458 day/L)*(49 ug/day)* (0.634 L milk/day/3.69 L) = 3.85 ug/kg/day (0.737 day/L)*(49 ug/day)* (0.634 L milk/day/3.69 L) = 6.20

ug/kg/day Calculation comparing infant exposure (calculated above) to the reference dose: 3.85 ug/kg/day / (0.7 ug/kg/day)= 5.5 6.20 ug/kg/day / (0.7 ug/kg/day)= 8.86]

* Infants are more susceptible to the serious neurological development effects of perchlorate, which can result in irreversible impacts. Due to their life stage, infants can suffer serious neurodevelopmental impacts because their central nervous system is still developing and is susceptible to small deficits of thyroid hormone level; they lack hormone reserves that adults have accumulated to buffer hormone deficits; and they may experience a slower clearance of perchlorate from their bodies.

Response: Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

Comment: Perchlorate and Iodine in infants

The CDC study does not capture either perchlorate exposure or thyroid hormone response in infants, which is an important sensitive subpopulation. A recent study measuring iodine intake in breastfeeding infants found that only 1 in 13 infants was receiving adequate levels iodine, based on Institute of Medicine Guidelines (Dasgupta et al. 2008). In fact, six infants in the lower half of the group were receiving only between 12 and 29% of the suggested intake values for iodine (Dasgupta et al 2008). In this same study, the ingestion of perchlorate in human milk exceeded the reference dose for perchlorate in 9 out of 13 infants. The concentrations of perchlorate and iodine reported in this study were generally similar to earlier studies, including Kirk et al. 2005 and 2007 and Blount et al. 2007.

EPA Comment Code: 5240

Comment: In addition to its preliminary determination not to regulate perchlorate in drinking water, EPA has proposed an HRL of 15 micrograms/L (ug/L, equal to parts per billion, ppb) of perchlorate in drinking water, assuming 62% of the daily perchlorate dose comes from water, and the rest comes from food.[FN4: 73 Fed. Reg. at 60275.][FN5: Calculation of the HRL: For all populations, including pregnant women, the RfD is 0.7 ug/kg/day. EPA reports that for pregnant women, exposure to perchlorate from food is 0.263 ug/kg/day at the 90th percentile, representing nearly 38% of the RfD, and thus leaving an RSC (relative source contribution) for water of 62% (FR at 60276). This is equavelent to 0.437 ug/kg/day from water, assuming an average body weight of 70 kg, and a daily water consumption of 2 L. That is, 0.437 ug x 70 kg body wt. = 30.6 ug perchlorate in 2 L (the daily consumption amount). This is 15 ug/L, or 15 ppb, the HRL.] The HRL "will be the basis for the health advisory value in the health advisory document the Agency expects to issue at that time. Thereafter, it may be appropriate to use the health advisory value as a "to be considered" (TBC) value in developing potential cleanup levels for perchlorate at Superfund sites."[FN6: Id. at 60265.] The HRL is not protective of sensitive sub- populations and EPA's own scientists have produced strong evidence using PBPK modeling that this level of water contamination would mean bottle-fed infants would exceed the EPA reference dose or 'safe' level of 0.7 ug/kg/day by five- fold, and young children would exceed the reference dose by 2.8-fold (based on average food contamination rates, average body weights, and 90th percentile water consumption rates for each age group). Furthermore, EPA's HRL determination did not include consideration of a subpopulation that is likely to be highly exposed to perchlorate and uniquely sensitive: the breast-feeding neonate.

Response: See response to comment code 5210 for a discussion of the RSC and response to comment code 5220 for a discussion of HRLs.

Comment: B. EPA's analysis fails to consider the health risks perchlorate poses to key sensitive sub-populations.

EPA has stated in its preliminary determination that the most sensitive subpopulations are women of reproductive age and the fetus. This determination improperly excludes consideration of other sensitive subpopulations including pre-term infants, neonates and breast-feeding infants. Recent studies demonstrate that infants born to low-iodide women are the most at-risk population, because of both high dietary exposures and because infancy is a highly sensitive developmental stage. Disruptions to normal hormone activity during this time is likely to result in permanent abnormalities. EPA has not adequately accounted for this sub-population in its analysis or its PBPK modelling.

Infants are routinely being exposed to unsafe levels of perchlorate and a major route of exposure is through contaminated breast milk. A collaborative study from the CDC and Boston University examined breast milk samples from 49 Boston area women and found the median breast milk perchlorate level was 9.1 ppb (range 1.3 to 411 ppb).[FN25: EN Pearce, AM. Leung, BC Blount, HR

Bazrafshan, X He, S Pino, L Valentin-Blasini, and LE Braverman, 2007. Breast milk iodine and perchlorate concentrations in lactating Boston-area women. J Clin Endocrinol Metab. 92(5):1673-7.]

To make matters worse, the Boston study found that 47 percent of the babies tested were not getting adequate levels of iodine from breast milk. Since the effects of perchlorate are compounded by insufficient iodide consumption, these babies are at even greater risk for thyroid hormone disruption. Notably, the Boston study also found that even moms who ingested extra iodine by using iodized salt or taking multivitamins containing iodine did not always have sufficient iodine in their breast milk. This finding underscores the need for the government to take effective actions to significantly reduce perchlorate contamination of food and drinking water.

The Boston study also measured perchlorate concentrations in the mother's urine, finding a median level of 3.0 ppb. More important than the actual values, however, is the fact that these concentrations are remarkably similar to levels of perchlorate found in the much larger Centers for Disease Control and Prevention (CDC) study of perchlorate exposure that tested the urine of more than 2,800 individuals.[FN26: Blount BC, L Valentin-Blasini, JD Osterloh, JP Mauldin, and JL Pirkle. 2007. Perchlorate exposure of the US population, 2001-2002. J Expo Sci Environ Epidemiol. 17(4):400-7.] In that study, the median urinary perchlorate concentration was 3.6 ppb. Since the perchlorate exposures in the two studies are so closely aligned, one can assume that the high levels found in the Boston women's breast milk are, unfortunately, likely to be typical of the general U.S. population.

Comment: C. EPA ignores data showing that pre-birth and newborn infants are a highly vulnerable sub-population based on health impacts.

EPA's preliminary regulatory determination focuses on the number of pregnant women who are affected by perchlorate contamination; but this analysis ignores the fact that prebirth and newborns are also a highly vulnerable subpopulation.

An earlier analysis by scientists with the CDC of a nationally representative sample of 2,299 U.S. residents greater than 12 years of age has documented that exposure to perchlorate poses potential health risks to women of child-bearing age and especially to their babies (hereinafter referred to as "Blount (2006)").[FN29: Blount BC, Pirkle JL, Osterloh JD, Valentin-Blasini L, Caldwell KL. Urinary perchlorate and thyroid hormone levels in adolescent and adult men and women living in the United States. Environ Health Perspect. 2006 Dec;114(12):1865-71.] These data were not available at the time of the NRC review, but have since been published. This study tested the association of chronic perchlorate exposure, as measured by urinary perchlorate excretion, with total serum thyroxine (T4) concentration, and thyroid stimulating hormone (TSH) concentration.

For women with low iodine intake (defined by the World Health Organization as urinary iodine < 100 ug/L),[FN30: World Health Organization (WHO). 1994. Indicators for assessing iodine deficiency disorders and their control through salt iodization. WHO/NUT/94.7. Geneva: WHO/International Council for the Control of Iodine Deficiency Disorders.] very low levels of perchlorate exposure were associated with decreased serum T4 and increased serum TSH; the CDC estimates that 36% of U.S. women have iodine intakes in this range. For iodine-sufficient women (defined as urinary iodine >= 100 ug/L), perchlorate exposure was associated with increased TSH. Increased TSH is an indicator that the body is attempting to compensate for a decrease in thyroid hormone production, and is clinically considered to be a more sensitive marker of subtle thyroid alteration than depressed levels of serum T4. When predicting changes in serum TSH with increasing perchlorate exposures, women with low iodine intake and TSH levels on the high end of the normal range (> 3.11 IU/L) appeared to be the most sensitive group. In this group, any increase in urinary perchlorate predicted an increase in TSH that was consistently more than twice the predicted increase in TSH for women with low iodine levels and median TSH levels. For unknown reasons, perchlorate was not associated with T4 or TSH levels in men. The observed changes in serum T4 and TSH in women are consistent with our understanding of how thyroid hormones are regulated in the body, and with the mechanism of toxicity of perchlorate.

Importantly, the extremely low levels of perchlorate were associated with thyroid hormone disruptions - and the magnitude of these disruptions. The CDC researchers found that if a low iodine woman started with perchlorate exposure corresponding to 0.19 ppb in urine (the minimum level found), and then ingested enough perchlorate through food and/or drinking water to raise her urinary perchlorate level to 2.9 ppb (the median level found), her T4 levels would drop by 13%.[FN31: The drop in T4 predicted to be 1.06 ug/dL; the percentage decrease is calculated as compared to the average T4 level found in the CDC study (8.27 ug/dL).] Similarly, if her urinary perchlorate level increased to 5.2 ppb (the 75th percentile exposure), her T4 levels would drop by 16%. The maximum level of perchlorate exposure found was 100 ppb, which translated into a 29% decline in T4.

The unique physiology of pregnancy and interactions between the mother and fetus makes both especially susceptible to the harmful effects of perchlorate. Maternal T4 is the only source of thyroid hormone for the fetus in the first trimester. Recent studies have shown that the cognitive development of the fetus is impaired in mothers with even mild disruptions in thyroid hormone levels, prompting the medical community to recommend thyroid hormone replacement therapy for pregnant women who are found to have sub-clinical hypothyroidism (mildly elevated TSH but normal T4).[FN32: Cooper, D. 2004. Sub-clinical thyroid disease: consensus or conundrum. Clinical Endocrinology 60 (410-412); Haddow JE, Palomake GE, Allan, WC, Williams JR, Knight GJ, and Gagnon J, et al. Maternal thyroid deficiency during pregnancy and subsequent neuropsychological development of the child. New England Journal of Medicine 1999: 341: 549-555; Pop VJ, Kuijpens J., van Baar, AL, Verkert, G. et al. 1999. Low maternal free thyroxine concentrations during early pregnancy are associated with impaired psychomotor development in infancy. Clinical Endocrinology 50 (149); Surks M., Ortiz E., Daniels G., Sawin C., Col N., Cobin R., Franklyn J. Hershman J., Burman K., Denke M., Gorman C., Cooper R., Weissman N. 2004. Subclinical Thyroid Disease. Subclinical Thyroid Disease. Journal of the American Medical Association 2004: 228-238.]

An analysis by Environmental Working Group reported that if the CDC's results for low iodine women with high-normal TSH levels are extrapolated to the general population, one would expect

more than 2 million women in the U.S. to become subclincally hypothyroidic as a result of drinking water contaminated with just 5 ppb of perchlorate.[FN33: Environmental Working Group. 2006. Thyroid Threat: Under Proposed Rocket Fuel Standards, Many Women Would Need Treatment To Protect Baby. Available at: http://www.ewg.org/node/20968] If these women became pregnant, they would require medical treatment to restore their thyroid hormones to normal levels and protect their babies from IQ deficits and abnormal development.

Comment: An MCL below 1 ppb is required to adequately protect vulnerable newborn babies and their recommended sole source of nutrition, breast milk

In June 2006, the State of Massachusetts (MA DEP) and its scientific advisors (MA DEP/DPH Advisory Committee) "unanimously concluded that [the RfD] did not fully account for the uncertainties surrounding science's understanding of perchlorate toxicity and exposures."[FN45: MA DEP, "Update To 'Perchlorate Toxicological Profile And Health Assessment'" March 2006, page xii.] Following recommendations from their scientific experts, MA DEP finalized a Perchlorate Maximum Contaminant Level for drinking water and a Perchlorate Cleanup Standard of 2 ppb based on a review and assessment of all data available at the time. Likely because the Blount (2006) data were not yet available, the MA DEP drinking water and cleanup standards failed to consider the special exposure patterns of infants born to low-iodide women, whom we now know are the most at- risk population based on both high exposure and vulnerability to permanent and severe neurological impacts. Therefore, an MCL must be below 1 ppb to be truly health protective.

Response: See response to comment code 6120.

EPA Comment Code: 5240

Comment: Having reviewed your letter in detail, I'll now address the specific issues raised.

1. You express concern with in utero and postnatal development, particularly neonates with greater exposure than adults and who lack stores of thyroid hormone.

Specifically, your letter states that EPA's HRL of 15 μg/L is a flawed benchmark and would allow daily exposures to infants that are 2-5 times higher than the Reference Dose (RfD) and that this lifestage must be adequately protected.

Based upon the conservative and health-protective NAS-based RfD and even more conservative Health Reference Level (HRL) benchmark, this lifestage will receive significant protection. The HRL relies on the NAS-recommended RfD that has several levels of caution built into calculation of the dose. The NAS report recommended an RfD of 0.7 μg/kg-d based on a level that causes no inhibition of iodine update or a No Observed Effect Level (NOEL)--the dose at which no effects occur, adverse or otherwise (NAS, 2005). The NAS panel stated that using a NOEL as the point of departure is a more conservative and health-protective approach than EPA's customary approach of using the adverse effect (i.e., using a dose at which there is no observable adverse effect level or the Lowest Observable Adverse Effect Level; (NAS, 2005). The NAS panel also took care to distinguish between a No Observable Adverse Effect Level (NOAEL) and a NOEL. The experts observed that there was confusion between the two and clarified that the NOAEL is based upon an adverse effect, whereas the NOEL is based upon a dose at which no effect occurs, adverse or otherwise. (NAS, 2005). EPA adopted the RfD recommended by the NAS and confirmed that it was conservatively based on the NOEL, not the NOAEL.

In using a NOEL, the NAS committee adopted a notably cautious, health-protective approach. In addition, the NOEL has an additional safety factor of 10 added this factor to ensure protection for the most sensitive individuals in a population, in this case, hypothyroid or iodine-deficient pregnant women and their developing fetuses. Importantly, the NAS panel did consider other sensitive populations in addition to pregnant women and their fetuses. They also considered the potential effect on infants, developing children, people who have compromised thyroid function, and people who are iodidedeficient. While it has been argued that the infant or child is the more sensitive individual in the population; experts from the NAS perchlorate panel, US EPA, CA OEHHA, and others agree that pregnant women and their fetuses are the most sensitive, thus these other sensitive groups would be protected if the most sensitive group is protected.

Response: The comment is addressed to the Children's Health Protection Advisory Committee, not to EPA, therefore, a response is not appropriate.

EPA Comment ID: 21023
EPA Comment Code: 5240

Comment: 6. Your letter states EPA's HRL is too high for infants and would allow daily exposures to infants that are 2-5 times higher than the RfD.

Perchlorate is not known or likely to occur in public water systems with high enough frequency nor does it occur at levels or public health concern. The NHANES studies and breast milk biomonitoring studies, notwithstanding their limitations, reveal that the US population is not exposed to levels of perchlorate that could cause an adverse effect, even when all exposure sources - in food and water - are considered. EPA's UCMR monitoring found a mean concentration of less than 10 ppb in systems with perchlorate - more than 100 times lower than the NAS' estimated effect level. Only a few systems have found any samples with concentrations greater than 100 ppb. Even the maximum level detected in the US is approximately 50 times lower than the dose at which the NAS panel estimated adverse effects could begin.

Response: The comment is addressed to the Children's Health Protection Advisory Committee, not to EPA, therefore, a response is not appropriate.

Comment: VI. Sensitive Subpopulations Could Be Exposed to Drinking Water with Greater than 15 ppb Perchlorate without Adverse Health Effects

As stated in these comments, in the Intertox summary, and in our comments to EPA's May 1st, 2007 notice, EPA should use an HRL equal to the RfD to reflect the conservative approach of the RfD and the ample evidence that exposure at the RfD have no effect on individuals, including sensitive subpopulations.

However, even if EPA uses its methodology in the final determination, EPA should use a larger Bin III subgroup to mitigate the potential limitations discussed previously. Using the sample group of females of childbearing age increases the sample size significantly. Switching the subpopulation of concern to women of childbearing age increases the sample size by five-fold, lowering the reliance on just a few observations. More importantly, it captures the subpopulation the NAS panel identified as the most sensitive - fetuses of women with low iodine consumption. The most critical period for the fetus in a woman with sustained iodine deficiency may even occur before she knows she is pregnant. As EPA notes, assigning one value for consumption, body weight, and other parameters to represent all of pregnancy is difficult. For these reasons, if EPA continues its approach, we recommend EPA use the HRL derived from the Bin III estimate of food consumption for all women of childbearing age.

Response: EPA agrees that would increase the population of interest from 97 to 503 but took a conservative approach in looking at women who knew they were pregnant during the NHANES survey. We also performed a curve fitting and an analysis to eliminate outliers. The calculated water dose of 0.559 vs 0.502 for pregnant women would have resulted in an HRL of 19 to 20 vs 15 using the pregnant population.

Comment: In responding to this threat, EPA must set a drinking water standard for perchlorate that protects the most vulnerable subpopulations, particularly pregnant women, fetuses, infants, and small children. By interfering with the thyroid's ability to take up iodide, perchlorate can suppress the development of thyroid hormones critical to growth, development, and metabolism. This puts fetuses and children at particular risk for learning and behavioral disabilities; impaired gait, vision, and hearing; and even mental retardation. Exposure calculations must therefore consider the ingestion rates for these populations, and the reference dose should consider the particular vulnerabilities of these age groups. EPA should also include in its calculations low birth weight babies and underweight infants, as these populations may be extremely vulnerable.

Response: See response to comment code 5220.

Comment: We disagree with the currently recommended HRL of 15 ug/L in drinking water. We have done a landscape scale analysis of newborn Low Birth weight in California counties in which perchlorate was detected in drinking water in at least 2 samples. Total number of counties included in the analysis was 13. Interestingly, at least one of the counties which we considered to have relatively high levels of perchlorate in the drinking water was included as a reference county in another study using the same health data, but using different methods to determine effect.

We used regression analysis correlating the incidence of very low birth weight (LBW), as determined by the California Department of health services, with the mean concentration of perchlorate in the

drinking water samples in which perchlorate was at or above the detection limit. We found a statistically significant positive correlation between the presence of perchlorate- contaminated drinking water and LBW percentage at the population level, even when taking a measure of poverty (%uninsured) into account. Notably, there seems to be no threshold for LBW effects (although the lowest mean concentration evaluated was 3 parts per billion [ppb] perchlorate) and the relationship saturated by 10 ppb perchlorate in drinking water. Note that the effect of perchlorate on low birth weight appears to saturate below the EPA recommended HRL, and had no detectable threshold for the data used. (The detection limit was between 2 - 4 ug/L) Not only is the recommended HRL above a level at which there appears to be a positive correlation with increased incidence of LBW in newborns, but it is well above the saturating dose. Thus using 15 ug/L as an inflection point to analyze the differences in effects for populations exposed to perchlorate in DW above and below 15 ug/L would be biasing the results of the study towards artificially finding no effect of perchlorate on LBW (a false negative).

Water Docket Environmental Protection Agency Mailcode 2822T 1200 Pennsylvania Avenue, NW Washington, D.C. 20460

Re: Docket ID No. EPA-HQ-OW-2009-0297

Submitted via www.regulations.gov

The Children's Environmental Health Network (the Network) appreciates the opportunity to comment on the importance of regulating perchlorate in drinking water. We wish to associate ourselves with the comments submitted by Clean Water Action, the Center for Public Environmental Oversight et al on this topic.

The Network is a national organization whose mission is to promote a healthy environment and to protect the fetus and the child from environmental health hazards. The Network's Board and committee members include internationally- recognized experts in children's environmental health science and policy who serve on key Federal advisory panels and scientific boards. We recognize that children, in our society, have unique moral standing. The Children's Environmental Health Network was created to promote the incorporation of basic pediatric facts such as these in policy and practice:

* Children;s bodies and behaviors differ from adults. In general, they are more vulnerable than adults to toxic chemicals. * Children are growing. Pound for pound, children eat more food, drink more water and breathe more air than adults. Thus, they are likely to be more exposed to substances in their environment than are adults. Children have higher metabolic rates than adults and are different from adults in how their bodies absorb, detoxify and excrete toxicants. * Children's systems, including their nervous, reproductive, digestive, respiratory and immune systems, are developing. This process of development creates periods of vulnerability when toxic exposures may result in irreversible damage when the same exposure to a mature system may result in little or no damage. * Children behave differently than adults, leading to a different pattern of exposures to the world around them. For example, they exhibit hand-to-mouth behavior, ingesting whatever substances may be on their hands, toys, household items, and floors. Children play and live in a different space than do adults. For example, very young children spend hours close to the ground where there may be more exposure to toxicants in dust, soil, and carpets as well as low-lying vapors such as radon, mercury vapor or pesticides. * Children have a longer life expectancy than adults; thus they have more time to develop diseases with long latency periods that may be triggered by early environmental exposures, such as cancer or Parkinson's disease.

Clear, sound science underlies these principles. A solid consensus in the scientific community supports these concepts.

The world in which today's children live has changed tremendously from that of previous generations. There has been a phenomenal increase in the substances to which children are exposed. According to the EPA, more than 83,000 industrial chemicals are currently produced or imported into the United States. Thousands of chemicals are ubiquitous in our environment worldwide. Traces of hundreds of chemicals are found in all humans and animals. Every day, children are exposed to a mix of chemicals, most of them untested for their effects on developing systems. Many of these chemicals are readily passed across the placenta to the fetus, to the infant via breast milk, or via toys and other children's products. Many of these chemicals are also ingested in food and water. Many also are absorbed by children through the lungs by respiration of contaminated air.

Response: No response necessary to the information provided by the commenter.

Comment: However, even if EPA proceeds with its determination not to regulate perchlorate and instead finalizes an HRL, that level must be adjusted to account for the actual data from the PBPK model showing that hundreds of thousands of infants would exceed the safe daily perchlorate intake levels at the proposed HRL.

These comments are respectfully submitted for your consideration,

Commenter Organization: Massachusetts Department of Environmental Protection (MassDEP)
EPA Document ID: EPA-HQ-OW-2009-0297-0495
EPA Comment ID: 28861
EPA Comment Code: 5240

Comment: Section III(B): Comments on Alternative Approaches for Calculating Health Reference Levels (HRLs)

1) MassDEP recommends that EPA use the approach to setting HRLs as shown in Section III, Subsection B-3.

2) We support EPA's reassessment of exposure assumptions for life stages, including fetuses of gestation week 40, infants and developing children. Application of EPA's Guidance on Selecting Age Groups for Monitoring and Assessing Childhood Exposures to Environmental Contaminants is appropriate along with application of EPA's Guidance for Risk Characterization to convey the variability in risk levels experienced by different individuals in the population. In doing so, EPA has appropriately taken into account specific and appropriate exposure values for many but not all potentially sensitive life stages. Because of the potential sensitivity of the early neonatal period from birth to several days thereafter, we believe that exposures to the bottle-fed 7- day old should also be considered. In EPA's Interim Drinking Water Health Advisory for Perchlorate, the 7-day old bottle-fed infant was estimated to have the highest perchlorate exposure per body weight.

Response: See response to comment code 5220. Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 μg/L to 47 μg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated

based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

EPA Comment ID: 28876
EPA Comment Code: 5240

Comment: Vulnerable populations have been considered since the first risk assessment in 1998. All of EPA's interim guidance and the current RfD (which is the basis for the 2008 HRL) are based on the most sensitive subpopulation, the developing fetus.

A small percent of those who commented on EPA's preliminary regulatory determination opined that the infant or child is the most sensitive population to perchlorate health effects; however, experts, including authoritative bodies such as the National Academy of Sciences (NAS) National Research Council (NRC) perchlorate committee as well as federal and state agencies such as the EPA, the Agency for Toxic Substances and Disease Registry (ATSDR), the California Environmental Protection Agency Office of Environmental Health Hazard Assessment (OEHHA), and others, conclude that the fetus is the most sensitive population to protect (all others being less sensitive than the fetus are therefore protected). Furthermore, questions about alternative life stages being more sensitive to perchlorate exposure have been addressed in the past; EPA began focusing on the most sensitive life stage as the foundation of health protection as early as 1998 in its first risk assessment (U.S. EPA, 1998a).

Response: Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination.

Comment: Some have opined that the infant is the most sensitive individual in the population, but no scientific basis for this has been presented. The weight of evidence shows that the fetal brain is more sensitive to hypothyroidism than the neonate or infant brain (Boelaert and Franklyn, 2005).

There is no scientific evidence presented in the Notice that demonstrates that other life stages are more sensitive with regard to the development of health protective toxicity guidelines values than the fetus.

The NRC considered all possible sensitive populations in addition to pregnant women and their fetuses; this included infants, developing children, people who have compromised thyroid function, and people who are iodide-deficient, as sensitive to perchlorate exposure. Based on its assessment, the NRC committee states that "...fetuses and preterm newborns constitute the most sensitive populations although infants and developing children are also considered sensitive populations" (NRC, 2005). The purpose of defining an RfD based on "the most sensitive population" is that all other populations, including those that are more sensitive than average (but less sensitive than the most sensitive), would not be expected to have adverse effects, including at doses that exceed the RfD. To date-and with substantial scientific justification-the EPA, ATSDR, the states of California, Massachusetts, and New Jersey all regard fetuses to be the most sensitive population for health effects evaluations.

The RfD is an estimate or a representation of the acceptable level of risk for a lifetime of exposure. It is not a threshold above which adverse effects occur.

Reliable scientific studies published since NRC (2005) continue to demonstrate that no observable effect occurs at doses below the RfD. On a weight-of-evidence basis, the scientific literature demonstrates no significant health risk to the most sensitive individuals who consume water on a daily basis over a lifetime at environmentally relevant doses. Overall, these studies demonstrate that perchlorate is a ubiquitous chemical. It is naturally formed and is ubiquitous in the environment (Dasgupta et al., 2005), food (Murray et al., 2008), and the human body (Blount et al., 2006; Pearce et al., 2007b).

The RfD is an estimate of the acceptable level of risk for a lifetime of exposure. It is not a threshold above which adverse effects occur. This is particularly true for the perchlorate risk assessment which is based on a NOEL, a more conservative POD than a NOAEL or LOAEL. EPA is correct in setting acceptable exposure levels with margins of safety. This allows, for example, an individual to consume a dose above the RfD on one day and ingest a lower dose on a subsequent day. When considering perchlorate, the issue relative to other chemicals is less of a concern: perchlorate is not metabolized, does not bioaccumualate, and the half-life is approximately 8 hours. Thus, in the rare instance of an exceedence of the RfD over the short term, perchlorate leaves the body quickly. Currently, EPA's use of a ten-fold intraspecies factor in the RfD effectively covers the potential for differences in sensitivity and exposure.

The RfD is based on a NOEL for IUI. IUI is not adverse. It is not scientifically justified to use drinking water rates for specific life stages to lower the HRL when the current RfD already has an OF applied to account for the most sensitive individuals. EPA offers no justification for why other life stages might be currently at risk or why additional protection is needed. EPA remarks "The NRC (2005) identified 'the fetuses of pregnant women who might have hypothyroidism or iodide deficiency' as 'the most sensitive population,' but also identified infants and developing children as additional 'sensitive populations.'" The purpose of defining an RfD based on "the most sensitive population" is that all other populations, including those that are more sensitive than average, would not be expected to have adverse effects, including at doses that exceed the RfD. In addition,

reporting that the HRL could be lower in a group that is not the most sensitive without scientific support is not in compliance with the scientific method.

Bereft of scientific evidence, the Notice fails to present justification to alter the HRL based on specific life stages, particularly when the current RfD already has an uncertainty factor applied to account for the most sensitive individuals.

The purpose of defining an RfD based on "the most sensitive population" is that all other populations, even if they are more sensitive than average, would still be unlikely to suffer adverse effects, even at doses that exceed the RfD.

Response: EPA disagrees, the life stages at which individuals are most sensitive and therefore at greatest risk of adverse effect (the fetus, infant, and developing child) are inherently less than a lifetime. See response to comment ID 28338 under comment code 5225. Since the NRC also identified infants and developing children as additional life stages, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for pregnant women where EPA used a 90^{th} percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts. EPA is evaluating these potential alternative HRLs and considers them to be levels of public health concern for purposes of this determination. See response to comment 5220.

EPA Comment Code: 5300 SDWA Criterion #3 – EPA's determination that regulating perchlorate with a NPDWR would not represent a meaningful opportunity to reduce health risks for persons served by public water systems

Response to Code 5300: Using the criteria mandated by the 1996 SDWA Amendments EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems and has decided to begin development of a national primary drinking water regulation for perchlorate. See response to comment code 6120.

EPA Comment ID: 20272
EPA Comment Code: 5300

Comment: Second, Rubin, etal (see reference 2 electronic attachment - "Rubin trade off health risk final.pdf") [see PDF of docket ID EPA-HQ- OW-2007-0068-0163] have documented quantitative evidence that when regulatory costs increase in the order of $25 per month, significant numbers of customers are forced into spending choices that have health outcomes that may outweigh the projected benefits of the regulation. NRWA strongly feels that when evaluating whether a regulation will result in a meaningful health benefit, EPA must take these effects into consideration. This is essentially an affordability issue and NRWA recommends that EPA include appropriate affordability criteria in its CCL evaluation and its future determinations when regulating or not regulating perchlorate.

Response: EPA has determined that the following three SDWA criteria for regulatory determination have been met for perchlorate: (1) It has an adverse effect on the health of persons; (2) It is known to occur in public water systems with a frequency and at levels of public health concern; and (3) In the sole judgment of the Administrator, regulation of perchlorate presents a meaningful opportunity for health risk reduction for persons served by public water systems. . This action notifies interested parties of EPA's determination to regulate perchlorate, and thus imposes no requirements on public water systems. This action also initiates the process to develop a national primary drinking water regulation (NPDWR) for perchlorate. EPA will now begin developing a proposed NPDWR and Maximum Contaminant Level Goal (MCLG). EPA plans to publish the proposed NPDWR for public comment along with health risk reduction benefits, and cost analyses, feasibility analyses and other analyses required for regulatory development under the SDWA. In proposing an NPDWR the Administrator will also describe variance technology for perchlorate that the Administrator finds are available and affordable for public water systems of varying size, considering the quality of the source water to be treated.

Commenter Name: Michael Girard

EPA Comment ID: 20282
EPA Comment Code: 5300

Comment: EVALUATION OF POTENTIAL HEALTH EFFECTS ALONG WITH OCCURRENCE AND EXPOSURE RESULTS REVEALS THAT REGULATION OF PERCHLORATE WOULD NOT PRESENT A MEANINGFUL OPPORTUNITY FOR RISK REDUCTION

EPA establishes the HRL based on the RfD and the RSC and then compares the occurrence data to the health benchmark. Assuming an RSC of one (which yields an HRL of 24.5 ppb drinking water equivalent), the population exposed to perchlorate in drinking water above EPA's evaluative criteria - ½ and 1 times the health benchmark - are small fractions of the total population served by public drinking water systems. The populations exposed to perchlorate above these benchmarks is lower than the populations for other chemicals for which EPA has determined a drinking water standard would not reduce risk in a meaningful manner.

A comparison of occurrence data for perchlorate and relevant compounds from EPA's CCL 1 regulatory determinations and CCL2 proposed determinations reveals that perchlorate ranks as a lower opportunity for risk reduction than sodium, manganese, sulfate, and boron, all four of which EPA has made or proposed determinations not to regulate.

Further explanation of our evaluation of the third statutory criteria for meaningful opportunity for risk reduction is contained in Attachment 4 [See PDF of docket ID EPA-HQ-OW-2007-0068-0168].

Response: See response to comment ID 21028 under comment code 5200.

Comment: The third condition of the SDWA, that the Agency has a meaningful opportunity for health risk reduction, is also met for perchlorate. The setting of an MCL will trigger requirements for testing to determine whether there are exceedances, and fortunately, sensitive test methods and effective treatment systems are readily available. Therefore, the Administrator has the opportunity to intervene to protect the health of millions of pregnant women and their fetuses, and lactating women and infants across the country who would otherwise be exposed to unsafe levels of perchlorate.

Comment: 9. MassDEP Believes That a National Perchlorate Drinking Water Standard Provides a Significant Risk Reduction Opportunity. Table 2 of the Federal Register publication

provides information on the occurrence and population estimates for perchlorate above various thresholds. The table shows that up to 2.0 million people would be provided drinking water above 15 ppb, a value that, based on EPA's own estimates, is not protective of the breast or bottle fed infant, yet which is EPA's proposed HRL. EPA does not explain in the Federal Register how it reached its conclusion that protecting up to 2.0 million people is not a meaningful opportunity for risk reduction for persons, in particular infants, served by public water systems.

Response: EPA has determined that perchlorate meets the criteria for regulating a contaminant in Section 1412(b)(1)(A) of SDWA. As previously discussed in the Federal Register Notice, perchlorate may have an adverse effect on the health of persons and perchlorate is known to occur or there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern. Moreover, in light of the discussion in this notice and the information available at this time, the Administrator finds that regulation of perchlorate in drinking water systems presents a meaningful opportunity for health risk reduction for persons served by public water systems. Therefore, EPA will initiate the process of proposing a NPDWR for perchlorate. See response to comment code 6120 and 5220.

Comment: With respect to EPA-HQ-OW-2008-0068:

It is recognized that this issue has been a difficult one and much work on behalf of EPA with it's extensive resources and interest groups, the dominant ones also possessing significant resources. However, EPA's proposal to avoid regulation fails to meet the Agency's overarching mandate to protect human health and the environment. We know of specific cases where in fact perchlorate exposure has affected public health and in those cases, there is little choice but for the public to consume a basic resource made available by their communities or their other limited means of water supply.

Although considering the argument regarding significance of the percentage of water supplies affected accounting for a small percentage, EPA has inproperly weighted its importance. What it has thus done, is use a predjudiced method to arrive at a conclusion that by regulating perchlorate, it would have no material effect on improving human health. This is clearly incorrect as the data reviewed by the wider scientific community has concluded that there are negative health effects resulting from exposure, some of them quite serious. We further know through no small body of evidence that regulating contaminants has demonstrated, without question, the improvement on public health. By arbitrarily setting the criteria at some percentage affected is contrary to sound public health protection and contrary to the public's expectation for EPA.

For EPA to conclude based on the guidance criteria interpreted narrowly to mean that some percentage of affected are not significant is plainly contrary to the principles of the mandate to protect human health and the environment.

I encourage the Agency to reconsider this matter and set a national standard.

Comment: Given that the first two SDWA criteria have been met, and that there are available technologies to treat perchlorate, we believe that the third and final criterion has also been met and that a national standard set by the EPA presents a meaningful and appropriate risk reduction opportunity.

Further, a national standard is necessary to avoid a patchwork of potentially conflicting regulations amongst the various states . This is even more critical given that many states share water resources (such as the Colorado River water shared by Arizona and six other western states).

Therefore, we, the undersigned, request that the EPA reconsider its determination and establish a national maximum contaminant level for perchlorate

Respectfully,

Comment: Rubin, etal (see reference 1 electronic attachment - "Rubin trade off health risk final.pdf") [See PDF Docket ID EPA-HQ-OW-2008-0692-1669] have documented quantitative evidence that when regulatory costs increase in the order of $25 per month, significant numbers of customers are forced into spending choices that have health outcomes that may outweigh the projected benefits of the regulation. NRWA strongly feels that when evaluating whether a regulation will result in a meaningful health benefit, EPA must take these effects into consideration. This is essentially an affordability issue and NRWA recommends that EPA include appropriate affordability criteria in its final determination to not regulate perchlorate.

Comment: IV (C), p 60280. A meaningful opportunity for health risk reduction. When drinking water consumption estimates that are protective of the exposed population are included in the

population exposure estimates, the number of people exposed to estimated excessive levels of perchlorate is markedly increased. When it is considered that the population at risk is not pregnant women, but their fetuses - and we all are fetuses once in our life - the population at risk balloons. Therefore it seems to us that the opportunity for a meaningful health risk reduction has been greatly understated.

Comment: Fourth, since the scientific literature on perchlorate is extensive, EPA can rely on multiple approaches to determine that there would not be a meaningful opportunity for risk reduction through a national drinking water standard. As the PSG has stated in its public comments to EPA's May 1, 2007 notice (see attached)[No attachement provided], EPA reached its conclusions through several approaches, all with ample scientific justification. The literature on human health effects from perchlorate consists mainly of clinical, occupational, or ecological studies. There are also some well designed animal studies that have contributed to the health effects database. As EPA has stated repeatedly, PBPK modeling allows the agency to give policy officials more scientific support for interspecies and intraspecies uncertainty factors. Following EPA's first draft risk assessment for perchlorate in 1998, Dr. Curtis Klaassen, the Chair of the external peer review panel stated, "...a predictive risk assessment for perchlorate is possible and should be pursued in the next iteration of this assessment."[FN7: Curtis Klaassen, US EPA Perchlorate Peer Review Workshop, 1999.] EPA's consideration of its findings in its preliminary determination is exactly the use of compelling scientific information to support its policy decisions your November 5th letter [See PDF Docket ID EPA-HQ-OW-2008-0692-1749] endorses.

EPA Comment Code: 5300

Comment: While determining a "meaningful opportunity for risk reduction" is appropriately a policy decision it must be based on the best available scientific data. The best available data on perchlorate exposure suggest that very few individuals will be exposed to a dose of perchlorate greater than the RfD by drinking water with a perchlorate concentration above the HRL. Further, since the HRL is based on the NAS-recommended reference dose which is set at the no observed effect level (NOEL), which the NAS panel noted is a more conservative and health protective approach than using EPA's traditional approach of relying on the no observed adverse effect level (NOAEL)[FN9: NAS at 169, (pdf version).], along with an additional safety factor applied to it, the quantifiable incremental risk would appear to be very small.

Response: See response to comment code 5200. Regarding the comment about exposures above the RfD, the data underlying the definition of iodide uptake inhibition as a precursor effect and its relationship to the continuum of adverse thyroid outcomes reflects an understanding of effects in adults. The relationship of the precursor event to the adverse outcome in children has not been studied. Thyroid hormone status in neonates and infants is much less resilient than in adults. Generally speaking, they do not have iodide stores sufficient to offset the effects of reduced iodide uptake. Half-lives for circulating hormones are shorter than for adults, making infants and neonates less able to maintain stable hormone levels in the face of a chemical insult. The less resilient infant and neonatal system makes the exposure gap between a precursor event (iodide uptake inhibition due to perchlorate) and an adverse effect (reduced T3/T4 levels) much narrower than for adults. The distinction between the two may be blurred for the very young.

Eric Burneson Office of Ground Water and Drinking Water Standards and Risk Management Division Environmental Protection Agency

RE: [EPA-HQ-OW-2008-0068; FRL-8727-6] Drinking Water: Preliminary Regulation Determination on Perchlorate

The agency should adopt its determination not to enact a NPDWR for perchlorate on the basis of the authority to promulgate NPDWR under the Safe Drinking Water Act.

The agency's notice indicates that SDWA requires EPA to promulgate an NPDWR for a contaminate if three conditioned are identified: (a) The contaminate may have an adverse effect on the health of persons; (b) the contaminate is known to occur or there is a substantial likelihood that the containment will occur in public water systems with frequency and at levels of public health concern; and (c) in the sole judgment of the Administrator, regulation of such contaminate presents a meaningful opportunity for health risk reduction for persons served by public health water systems.

The research presented and previous comments do not clearly establish condition two, and by construction, condition three. Therefore EPA is not required to regulate perchlorate in public water systems.

U.S. Environmental Protection Agency Water Docket EPA Docket Center 1200 Pennsylvania Avenue, NW Washington, DC 20460

Letter to EPA re: Preliminary Regulatory Determination on Perchlorate (Docket ID No. EPA-HQ-OW-2008-0692)

Dear Administrator Johnson:

Environmental Working Group (EWG) strongly disagrees with EPA's recent finding that setting a national drinking water standard for perchlorate would not present "a meaningful opportunity for health risk reduction for persons served by public water systems" (EPA 2008). The science provides overwhelming evidence that the tens of millions of people drinking perchlorate in tap water face real health risks that only EPA can protect them from. But the agency has chosen not to act and by failing to act, EPA has sacrificed its scientific integrity.

Response: See response to comment code 5300.

Commenter Organization: New Mexico Environment Department
EPA Document ID: EPA-HQ-OW-2008-0692-1796
EPA Comment ID: 20938

EPA Comment Code: 5300

Comment: As to the third criterion, EPA concludes that a national primary drinking water regulation for perchlorate would not present a meaningful opportunity to reduce health risks for persons served by public water systems.[FN25: 73 Fed. Reg. at 60280.] EPA bases this conclusion on the flawed analysis, described above, in which the agency determined that perchlorate occurs only infrequently at levels of public health concern. EPA reiterated that of the 900,000 to two million people who may be ingesting public drinking water at levels above the HRL of 15 ug/L, "fewer than 30,000 of them are pregnant women at any given time."[FN26: Id.] EPA's conclusion fails to account for the reduced health risks to pregnant women in the future, and to their fetuses; to infants; and to persons with thyroid disorders.

Response: EPA believes that regulating perchlorate in drinking water presents a meaningful opportunity for health risk reduction and has decided to regulate perchlorate in drinking water. See response to comment code 6120.

EPA has made this determination based on a consideration of the best available peer reviewed science and data collected in accordance with accepted methods related to perchlorate occurrence in drinking water, the presence of perchlorate in foods, and the potential health effects of exposure to perchlorate.

EPA has determined that perchlorate meets the criteria for regulating a contaminant in Section 1412(b)(1)(A) of SDWA. As previously discussed in the Federal Register Notice, perchlorate may have an adverse effect on the health of persons and perchlorate is known to occur or there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern. EPA believes that the UCMR 1 is the best available data on the frequency and level of perchlorate occurrence in public water systems nationally. UCMR 1 indicated that 5.1 to 16.6 million people are served by PWSs, for which we have data, that have detected perchlorate above the minimum reporting level. In light of the discussion in this notice and the information available at this time, the Administrator finds that regulation of perchlorate in drinking water systems presents a meaningful opportunity for health risk reduction for persons served by public water systems. Therefore, EPA will initiate the process of proposing a NPDWR for perchlorate. See response to comment code 6120 and 5220.

EPA Document ID: EPA-HQ-OW-2008-0692-1988
EPA Comment ID: 20981
EPA Comment Code: 5300

Comment: The U.S. population is about 300 million people with about 6.8%, or 20 million, under 5 years old. On average, therefore, there are about 4 million kids in each year of life (from zero to five). With 4 million kids under 1 year old, including infants, there are 400,000 in the 90th percentile of water consumers, meaning that at the proposed HRL, these 400,000 would have a perchlorate intake, each day for their whole first year of life, that exceeds the reference dose. EPA's proposed model shows that there are 400,000 children under the age of 1 who would exceed the daily reference dose and this is likely underestimate of the highly exposed. Thus, the evidentiary record

does not support EPA's proposed determination. Rather, the evidentiary record makes clear that regulating these exposures does represent "a meaningful opportunity for health risk reduction for persons served by public water systems."

Commenter Name: Jennifer Sass, PhD.
Commenter Organization: Natural Resources Defense Council
EPA Document ID: EPA-HQ-OW-2008-0692-1988
EPA Comment ID: 21000
EPA Comment Code: 5300

Comment: The U.S. population is about 300 million people.[FN55: U.S. Census Bureau quick facts. 2006. http://quickfacts.census.gov/qfd/states/00000.html] Of the total, about 6.8%, or 20 million, are under 5 years old, an average of about 4 million kids of each year of life. This is a reasonable estimate supported by the fact that there were about 4,329,000 live births in the U.S. in 2007.[FN56: National Vital Statistics Reports, Vol 57, No 5. http://www.cdc.gov/nchs/data/nvsr/nvsr57/nvsr57_05.htm] If there are 4 million children less than 1 year old, including infants, then 400,000 of them would be in the 90th percentile of water consumers. This means that at the proposed HRL, 400,000 children and infants will exceed the reference dose for perchlorate every day for their entire first year of life.

As part of its basis for the preliminary determination not to regulate perchlorate because it does not feel there is a meaningful opportunity to reduce health risks, EPA acknowledged that perchlorate could have an adverse effect on human health.[FN57: 73 Fed. Ref. at 60275.]

Furthermore, EPA's own staff experts have provided data to show that at the HRL, 400,000 infants and children would consume perchlorate on a daily basis that exceeded the reference dose. Rather, EPA states that 30,000 pregnant women would be exposed to these levels of perchlorate, and that number does not provide a meaningful opportunity to reduce health risks. While we take issue with EPA's determination that reducing the exposure of 30,000 pregnant women to perchlorate is not meaningful, EPA must explain why reducing the exposure of 400,000 children and infants to perchlorate is not a meaningful opportunity to reduce health risks.

EPA Comment Code: 5300

Comment: 12. Finally, your letter argues that the "meaningful opportunity for risk reduction" criterion is met because an MCL will trigger testing for exceedances.

While determining a meaningful opportunity for risk reduction is appropriately a policy decision it must be based on the best available scientific data. The best available data on perchlorate exposure suggest that very few individuals will be exposed to a dose of perchlorate continuously for years greater than the RfD by drinking water with a perchlorate concentration above the HRL. Further, since the HRL is based on the NAS-recommended RfD which is set at the NOEL, which the NAS panel noted is a more conservative and health protective approach than using EPA's traditional approach of relying on the no observed adverse effect level (NOAEL) [FN10: NAS at 169, (pdf version).], along with an additional safety factor applied to it, the quantifiable incremental risk would appear to be small.

I hope you find these comments helpful; we would be happy to talk further with you about this important issue. Further, if the CHPAC opts to convene a public meeting on perchlorate, the PSG would welcome an opportunity to present the scientific literature and our public comments. For your convenience, we have included those comments for your review. Our comments review the science of perchlorate beginning with the comprehensive NAS review followed by subsequent studies and then apply them in the statutory and policy framework in which EPA has made its preliminary determination. Thank you for your time and attention.

Sincerely, Michael Girard Chairman, Perchlorate Study Group cc: Marcus Peacock, Deputy Administrator Benjamin Grumbles, Assistant Administrator, Office of Water Cynthia Dougherty, Director, Office of Ground Water and Drinking Water Eric Burneson, Chief, Targeting and Analysis Branch

EPA Comment ID: 21090
EPA Comment Code: 5300

Comment: Public water systems do not offer a meaningful risk reduction opportunity since EPA's data show that only a few percent of systems have had detectable levels of perchlorate and virtually all of them are routinely below EPA's unusually protective reference dose (RfD). EPA also has extensive data that show the US population's total exposure to perchlorate - from food and water - is below the RfD for 99.996 percent of the population. EPA should spend its limited resources on significant potential threats to human health in order to most effectively protect the public health.

The comments below present a detailed analysis of the issues relating to EPA's determination. The attachment from Intertox describes in more detail the state of the scientific literature. The overwhelming weight of scientific evidence indicates that EPA is acting correctly in its determination not to establish a Federal drinking water standard.

Response: See response to comment code 5200.

Comment: IV. The Scientific Literature Supports EPA's Findings that There is Not a Meaningful Opportunity for Risk Reduction from a National Drinking Water Standard

The evaluation of data on the health effects of perchlorate, national occurrence, and exposure using the SDWA "meaningful risk reduction" criteria support EPA's determination that an NPDWR for perchlorate is unnecessary.

Following the release of the NAS report, EPA set an RfD for perchlorate at 0.7 ug/kg-d. The RfD is defined as "...an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime (EPA, 2005). The RfD does not distinguish between perchlorate in drinking water and in food. In establishing the amount of perchlorate that would be expected to pose no risk to health in drinking water alone, the RSC is factored in resulting in the HRL or "the benchmark against which EPA compared the concentration of a contaminant found in public water systems to determine if it is at a level of public health concern (73 FR 60275)." EPA has established that it would not be meaningful to set an NPDWR, but is now considering issuing a Health Advisory (HA), in the form of an MCLG.

If EPA decides a Health Advisory is necessary, the RfD is sufficiently conservative to serve as the HA. As presented in the PSG's comments on the May 1, 2007 notice, the best available scientific analysis demonstrates that all of EPA's approaches lead to an RSC of essentially one. Drinking water is not a meaningful contributor to total perchlorate exposure - and not even a minor source of total inhibition of iodine uptake, the non-adverse effect that is the basis of the RfD.

Alternatively, the HRL identified in its preliminary determination could also serve as an even more conservative, but no more protective, HA. What is striking is that either approach would be highly conservative. In fact, the high level of conservatism, and health protection, is far greater than EPA indicated by the agency's longstanding policies, themselves properly weighted toward greater protection.

The HRL relies on the NAS-recommended RfD that has several levels of conservatism (that is, exceptional health protection) built into calculation of dose. As EPA has noted, its RfD was based upon the recommendations of the NAS which, as noted, used a much more conservative and health-protective approach to derive its recommended safe dose than EPA has previously used.[FN3: NAS, at 170-71.] EPA embeds an additional level of conservatism in calculating the final

HRL by verifying their calculations using PBPK modeling of pregnant women as opposed to relying on the standard of assuming an adult as the focus of its calculations.

To determine the RSC, the EPA uses the NHANES-UCMR data to estimate doses to people who were exposed through food only (73 FR 60273). The UCMR 1 shows the median concentration of perchlorate in drinking water to be 6.4 ug/L (73 FR 60269). The 90th percentile estimated dose to the women exposed only through food was 0.263 ug/kg/d which corresponds to 38% of the RfD. This leaves 62% of the RfD left for exposure through water. Using this data, a HRL was calculated as such:

HRL = (RfD x BW / DWI) x RSC Where, RfD = 0.7 mg/kg-d BW = 70 kg DWI = drinking water intake = 2 L/d RSC = 62%

This results in a HRL of 15 ppb. The derivation of the HRL was based on the body weight and water intake of an adult[FN4: The standard EPA default procedure for converting dose into drinking water equivalent levels assumes 2 liters (67.6 oz) of water consumed per day and a body weight of 70 kg (154 lbs). These default values are not symmetrically representative of the population. This water consumption (WC) default is approximately equal to the 88th percentile water intake for adults aged 20 through 64 (calculated from Table 3-11 of U.S. EPA's Exposure Factors Handbook; EPA, 1999). However, the default body weight of 70 kg is approximately equal to the 27th percentile of the distribution for adult males aged 18-74 and the 70th percentile of the distribution for adult females (from EPA, 1999; Tables 7-3 and 7-4).], not the pregnant woman and her fetus. The EPA modeled the amount of IUI in a pregnant woman and her fetus using PBPK modeling and found that the amount of IUI expected was equivalent to the NOEL from Greer et al. (2002). EPA then compares this HRL to perchlorate occurrence data in drinking water to evaluate the percent of the population exposed to perchlorate above the HRL.

For the perchlorate determination, EPA may also use the evaluation criteria under the CCL 1 regulatory determinations to determine whether a meaningful opportunity to regulate health risk exists. EPA's regulatory evaluation process follows the recommendations on a protocol from EPA's stakeholder advisory panel, the National Drinking Water Advisory Council (NDWAC). To assist EPA in evaluating the third statutory criteria, the NDWAC protocol recommended "that EPA consider estimating the national population exposed above half the health reference level (or benchmark) and the national population exposed above the health reference level (or benchmark)."

EPA used this approach for evaluating substances in its CCL 1 regulatory determinations. This approach allows EPA's decision-making process to be replicated and therefore provides greater transparency and objectivity into the agency's final decisions rendered on the third statutory criterion. It also has the support of major stakeholders and has been subject to public comment. The PSG points out that EPA could, in addition to its valid reasoning in the preliminary determination, relay a similar evaluation process for its perchlorate determination.

A comparison of occurrence data for perchlorate and relevant compounds from EPA's CCL 1 regulatory determinations and the CCL 2 determinations reveals that perchlorate ranks as a lower opportunity for risk reduction than the sodium, manganese, sulfate, and boron, all of four of which EPA has made determinations not to regulate.

If the HRL is 15 ppb, EPA estimates that between 0.29 percent and 0.8 percent of PWSs have at least one detection greater than 15 ug/L, affecting 0.9 million to 2 million people served. Between 1.14 percent and 2.12 percent of PWSs had at least one detect with concentrations at 1/2 of the HRL (7 ug/L), affecting between 0.8 percent and 2.5 percent of the population served or between 2.2 million and 7.2 million people served, respectively.

[Table 1: Comparison of Risk Opportunity between Perchlorate and Other Compounds - See PDF Docket ID EPA-HQ-OW-2008-0692-1855]

The percentage of PWSs with perchlorate detections was very low (3.6 percent) compared to the next lowest unregulated compound, manganese at 68 percent. Sodium, for example, was detected in all PWSs. Perchlorate also has one of the lowest populations served by PWSs with detections above half the HRL with 2.2 million people. Perchlorate is well within the range of values for the evaluation criterion EPA uses. Like these other constituents, perchlorate is widely found in the diet and has minimal adverse health effects at the RfD. Although EPA's approach of using actual food data has more scientific justification, even if EPA adopts its customary approach for the proposed regulatory determination, it should find that perchlorate does not pose a meaningful opportunity to reduce risk.

Response: See response to comment codes 5300 and 5200. EPA considered national occurrence and the severity of health effects from perchlorate and concluded that regulation was warranted, so EPA has determined that perchlorate should be subject to an NPDWR. The Agency plans to prepare and make available a regulatory health effects support document as part of its regulatory promulgation process. If an NPDWR is promulgated a health advisory will be unnecessary. EPA agrees with the commenter that the RfD is conservative and protective of health.
Regarding the PBPK model, after further consideration of the peer review and public comments, EPA concludes that the PBPK modeling analysis, in the context of the perchlorate regulatory determination, is useful in examining which life stages are most susceptible to the effects of perchlorate. For example, the model indicates that a fetus may be seven times more sensitive to the effects of perchlorate than a pregnant woman. The model also allows for the estimation of the concentration of perchlorate in breast milk (thus breast-fed infant exposure) at various maternal perchlorate exposure levels. However, because of the stated limitations, EPA has decided the model does not directly bear on the current decision regarding the need for a NPDWR for perchlorate. EPA is continuing to evaluate whether the model could be used in setting a NPDWR for perchlorate. Regarding the suggestion to compare the risk opportunity from detects in public water systems between perchlorate and other compounds that EPA has decided not to regulate, EPA does not believe it's appropriate to factor these comparisons into the decision whether to regulate a contaminant. The Administrator will make these determinations on a case-by-case, contaminant specific basis. In making a regulatory determination, the Administrator considers the adverse health effect of the particular contaminant at issue as well as the occurrence or likelihood of occurrence of the contaminant in public water systems with a frequency and at levels of public health concern. In addition, even if such comparisons were appropriate, the occurrence level of perchlorate at the levels of public concern identified by EPA are higher than most of the contaminants for which EPA has made a negative determination. Finally, it is the sole judgment of EPA's Administrator to determine whether there is a meaningful opportunity to reduce health risk for persons served by public water systems.

EPA Comment Code: 5300

Comment: In this time of severe economic stress in our society, it is particularly important that the benefits of a regulation be carefully weighed against the costs and only those with an overriding benefit/cost advantage be promulgated. For perchlorate it is clear that this advantage does not exist uniformly and in fact, for some communities the aforementioned reference provides evidence that the adverse health effects caused by the cost of the regulation may equal or outweigh the projected benefits.

Rubin, etal (see reference 1 electronic attachment - "Rubin trade off health risk final.pdf") have documented quantitative evidence that when regulatory costs increase in the order of $25 per month, significant numbers of customers are forced into spending choices that have health outcomes that may outweigh the projected benefits of the regulation. NRWA strongly feels that when evaluating whether a regulation will result in a meaningful health benefit, EPA must take these

effects into consideration. This is essentially an affordability issue and NRWA recommends that EPA include appropriate affordability criteria in its final determination to not regulate perchlorate.

Comment: c) The SDWA requires that the regulation of such contaminants must present a meaningful opportunity for health risk reduction for persons served by public water systems. For perchlorate, no possible health benefit can occur when estimated exposure levels are below the NOEL for a nonadverse effect. Further, EPA adjusted the NOEL ten-fold lower to derive the RfD to account for sensitive subpopulations.

Comment: 4) ACWA believes that the maximum contaminant levels (MCLs) established in Massachusetts and California have significantly reduced the current public exposure to perchlorate in drinking water. ACWA feels this has had an impact on the meaningful opportunity for health risk reduction that is available through a national drinking water standard for perchlorate.

Response: EPA acknowledges that there may be sources that had detected perchlorate from UCMR1 monitoring are either no longer being used or are being treated per the requirements of maximum contaminant levels established in California and Massachusetts; however, the 1996 amendments to the Safe Drinking Water Act require the Agency to consider the best available, peer reviewed science when developing drinking water standards. In applying these principles, "best available" usually refers to the availability at the time an assessment is made. See response to comment code 5300.

Commenter Organization: Pacific Institute
EPA Document ID: EPA-HQ-OW-2008-0692-1770
EPA Comment ID: 29099
EPA Comment Code: 5300

Comment: We understand the need to balance costs and benefits in drinking water regulations, however, costs associated with the regulation of perchlorate will ostensibly be low, except in those cases where high levels of perchlorate exist and drinking water must be treated. For other systems, costs can be limited to periodic monitoring (e.g., once in every 4 years, as is done with

radionuclides). The cost of regulating perchlorate in our country's public drinking water, when compared with the myriad potential health-related costs, including added pressure on public health care systems, missed work and school days due to sickness, etc., may very likely prove the most cost-effective option.

In light of these concerns we sincerely hope that the EPA reevaluates its Preliminary Decision, taking into account the impact of this regulation on all vulnerable populations, the potential for remediation efforts, and the potential future contamination of drinking water. In addition, we hope that the agency fulfills its duty to protect the public health of the thousands of individuals who are affected by unsafe perchlorate exposure through public drinking water.

Sincerely, Lucy Allen Research Analyst Pacific Institute

Courtney Smith Research Analyst Pacific Institute

Response: Regarding the costs associated with regulating perchlorate, see response to comment ID 20272 under comment code 5300. Regarding EPA reevaluating its preliminary decision, see response to comment code 5300.

EPA Comment ID: 28485
EPA Comment Code: 6000

Comment: The significance of this issue goes far beyond setting unwise regulatory precedent. An overly conservative perchlorate standard that is not based on sound, peer-reviewed science and an appropriate risk-based assessment could unintentionally lead to unjustified food scares on a wide variety of fresh fruits, vegetables, and dairy products. Food scares of this nature could where particular commodities are "black listed" without regard to science would have devastating economic impacts on agriculture producers and processors. Finally, the economic impacts associated with unfounded concerns over traces of perchlorate in food could lead to the relocation of agricultural production to countries that have food safety standards that are significantly lower than in the United States.

We appreciate your attention to our concerns and once again encourage you to extend the comment period for an additional 30 days.

Sincerely, Stephen Haterius Executive Director

Response: EPA believes that perchlorate meets the specific criteria for regulating a contaminant in Section 1412(b)(1)(A) of the Safe Drinking Water Act and therefore has determined that EPA should regulate perchlorate in drinking water. EPA discusses this conclusion in more detail in today's perchlorate Federal Register notice. EPA agrees that perchlorate is more widespread in foods than in public water systems, but EPA does not believe that the widespread presence of perchlorate in food overrides the opportunity for public health risk reduction for persons served by public water systems with perchlorate contamination. EPA's action considers the presence of perchlorate in food but would not impose regulatory requirements on perchlorate in food. Regulation of perchlorate in foods is outside the scope of this determination which is made under the authority found in the Safe Drinking Water Act, as amended in 1996.

U.S. Environmental Protection Agency Mailcode 2822T 1200 Pennsylvania Ave., NW. Washington, DC 20460

Subject: Docket ID No. EPA-HQ-OW-0297

Reference: Drinking Water: Perchlorate Supplemental Request for Comments (Federal Register / Vol. 74, No. 1591 Wednesday, August 19, 2009 / Notices

Attached, please find comments provided by the Nevada Division of Environmental Protection (NDEP) in response to the referenced "Supplemental Request for Comments" noticed by the U.S. Environmental Protection Agency (EPA) in the August 19, 2009 Federal Register; Docket ID No. EPA-HQ-OW-2009-0297. These comments are provided to assist the EPA in their efforts in evaluating whether there is a meaningful opportunity for human health risk reduction of perchlorate through a national primary drinking water rule.

The NDEP understands that in order to regulate a contaminant in drinking water [i.e., develop a maximum contaminant level (MCL)], EPA must determine that the contaminant meets the following three criteria:

1) The contaminant may have an adverse effect on human health;

2) The contaminant is known to occur (or there is a substantial likelihood that the contaminant will occur) in public water systems, with a frequency and at levels of public health concern; and

3) Regulation of such a contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems

The NDEP believes that the EPA cannot reliably demonstrate that all three criteria can be met (with respect to perchlorate) when all of the studies and available literature are used and new occurrence data are collected to inform the decision. Many studies have been conducted and the results peer reviewed and published since the National Academy of Science (NAS), National Research Center (NRC) provided their review in 2005. A number of these studies were conducted explicitly to fill data gaps present at that time. A thoughtful review of the entirety of the studies and literature, coupled with collection and analysis of up-to-date occurrence data, is recommended to allow EPA to meet its charge on this important decision.

Response: EPA has continued to review all the available data published concerning perchlorate in drinking water as it is made available. The regulatory determination made in today's Federal Register notice was based upon a consideration of the best available peer reviewed science and data, both recent as well as the information available and discussed in earlier Federal Register notices.

EPA Comment Code: 6110 Comments urging EPA not to regulate perchlorate

Response to Code 6110: After review of the available science, data and public comments, EPA has determined that perchlorate may have an adverse effect on the health of persons and that perchlorate is known to occur or there is a substantial likelihood it occurs in public water supply systems with frequency and at levels of public health concern. EPA has also determined that regulation of perchlorate presents a meaningful opportunity to reduce health risk for persons served by public water systems. The basis for EPA's determination is described in the Federal Register Notice for the final regulatory determination.

US Environmental Protection Agency Office of Water Docket (Mailcode 2822T) 1200 Pennsylvania Avenue, NW Washington, DC 20460

RE: Comments on Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant Candidate List Rule Docket EPA-HQ-OW-2007-0068

The Perchlorate Study Group (PSG) is pleased to submit comments to EPA on Docket ID No. EPA-HQ-OW-2007-0068, entitled Drinking Water: Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant Candidate List- Preliminary Determinations; Proposed Rule.[FN1: 72 Fed. Reg. 24015 (2007) (proposed May 1, 2007).]

The PSG is committed to ensuring that the best available science is made available in public debate and in the subsequent setting of regulatory standards.[FN2: In section 1412(b)(3)(A) of the 1996 Amendments to the Safe Drinking Water Act, Congress required EPA to use the best available science and data: "The Administrator shall use: (i) the best available, peer-reviewed science and supporting studies conducted in accordance with sound and objective scientific practices; and (ii) data collected by accepted methods or best available methods (if the reliability of the method and the nature of the decision justifies use of the data).] The member companies of the PSG include Aerojet, AMPAC, ATK, and Tronox.

The PSG has worked cooperatively and effectively with the US Environmental Protection Agency (EPA) and other federal agencies, state governments, water purveyors, and other business organizations to:

* increase scientific and medical understanding of perchlorate's possible effects on human health; and,

* assess the level of perchlorate in drinking water that will pose no cognitive risk.

In seeking public comment on its Second Contaminant Candidate List (CCL 2) Preliminary Determinations, EPA has expressed particular interest in receiving information regarding the adequacy of available occurrence and exposure data with respect to making a regulatory determination for perchlorate. In addition, EPA has asked for public input on scientific analysis options that would assist the Agency in reaching a regulatory determination for perchlorate.

The PSG members are manufacturers and users of perchlorate who are actively remediating areas of past releases, and are citizens concerned with the protection of the public's health. As such, the PSG member companies have a strong and unique commitment to ensuring that the best available science is applied in regulatory decision making.

Based on its thorough evaluation of the best available science, as well as consideration of the Agency's statutory authorities, the PSG respectfully submits:

* in light of the National Academy of Sciences comprehensive review, as well as numerous, peer-reviewed studies, the Agency has more than sufficient data on perchlorate's human health effects to make a regulatory determination for perchlorate on an expedited basis; and

* the extensive scientific record indicates that establishing a drinking water standard for perchlorate would not yield a meaningful opportunity to reduce risk to human health, as required under the Safe Drinking Water Act.

ANALYSIS AND OBSERVATIONS

EVALUATING THE 3 STATUTORY CRITERIA FOR THE REGULATORY DETERMINATION PROCESS

To determine whether to regulate a contaminant with a Federal drinking water standard, EPA evaluates three Safe Drinking Water Act criteria.[FN3: In section 1412(b)(1)(A) of the Safe Drinking Water Reauthorization Act of 1996, Congress established three criteria for use by EPA in making drinking water regulatory determinations: (i) the contaminant may have an adverse effect on the health of persons; (ii) the contaminant is known to occur or there is a substantial likelihood that the contaminant will occur in public water systems with a frequency and at levels of public health concern; and, (iii) in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems. (See, 110 Stat. 1613, 1619; 42 USC. §300g-1(b)(1)(B)(ii)(II)).] EPA has determined that it must make an affirmative determination on all three criteria to move forward with regulation. If the Agency determines that a regulation is appropriate, EPA can make its regulatory determination for perchlorate in two ways:

1. through its longstanding approach used in the CCL 1 rulemaking and proposed for the CCL 2 determinations; or,

2. applying supplemental or alternative approaches reflecting new scientific information, using the uniquely conservative derivation of the perchlorate reference dose (RfD) for perchlorate, as well as the exceptionally deep and authoritative scientific literature on toxicity and population exposure.

No matter which approach EPA takes, the best available science runs inevitably to the conclusion that a perchlorate standard will not yield a meaningful opportunity to reduce risk to human health as required by the Safe Drinking Water Act.

EPA has more than sufficient data on perchlorate's human health effects as well as on occurrence and exposure to make a determination on perchlorate without delay. EPA is to be commended for its efforts to obtain public comment relating to the prospective use of supplemental or alternative approaches. These approaches are scientifically rigorous and upto- date, based on the peer- reviewed literature. Our collective goal of applying the best available science would point toward their use.

Nonetheless, should the agency elect to apply an approach based strictly on toxicology and modeled exposures, we anticipate it will yield the same conclusions, albeit, after a period of unnecessary delay.

Response: Please see the response to comment code 6110.

EPA Comment Code: 6110

Comment: CONCLUSION

In summary, EPA has an extraordinary wealth of comprehensive, authoritative scientific information relating to perchlorate's health effects, supplemented by extensive occurrence and exposure data. The Agency is therefore exceptionally well-positioned to issue a wellconsidered regulatory determination.

In this case, the Agency can rely on the scientific review by the NAS and its own subsequent analysis in setting a reference dose pursuant to the NAS Report. Subsequent, peer-reviewed studies provide additional information that corroborates the conclusions of the NAS and EPA.

The Agency can use its RfD as the HRL. EPA should take into account that the RfD is based on an unusually conservative point of departure, a NOEL (as opposed to the Agency's customary No Observed Adverse Effect Level), with an added safety factor of 10.

Ultimately, regardless of which approach EPA takes, the best available scientific data supports a determination that there is not a meaningful opportunity for risk reduction as required by the Safe Drinking Water Act.

The Perchlorate Study Group appreciates the opportunity to submit comments on this issue. If you have any questions regarding these comments, please do not hesitate to contact Michael Girard at (916) 355-2945.

Response: Please see the response to comment code 6110. In light of the discussion presented in the final regulatory determination notice and the information available at this time, EPA expects to select an MCLG from among the range of potential alternative HRLs in the August 9, 2009 notice (74 FR 41883). These levels range from 1 μg/L to 47 μg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals in each life stage.

Comment: November 10, 2008 U.S. Environmental Protection Agency Office of Water Docket (Mailcode 2822T) 1200 Pennsylvania Ave. NW Washington, DC 20460

RE: Drinking Water: Preliminary Regulatory Determination on Perchlorate Docket EPA-HQ-OW-2008-0692

The American Water Works Association appreciates the opportunity to comment on the preliminary regulatory determination for perchlorate as detailed in the October 10, 2008 Federal Register notice (73 FR 60262). AWWA is an international, nonprofit, scientific and educational society dedicated to the improvement of drinking water quality and supply. Founded in 1881, the Association is the largest organization of water supply professionals in the world. Our 60,000 plus members represent the full spectrum of the drinking water community: treatment plant operators and managers, environmental advocates, engineers, scientists, academicians, and others who hold a genuine interest in water supply and public health. Our membership includes more than 4,700 utilities that supply roughly 80 percent of the nation's drinking water. Based on this broad membership base, these comments should be considered as representative of the drinking water community in general.

AWWA has always been a strong' advocate of the process established under Section 1412(b) of the 1996 SDWA Amendments to ensure that appropriate and scientifically based standards are developed and enforced by the Agency. The SDWA defined three (3) key criteria for identification of contaminants for potential regulation:

i.the contaminant may have an adverse effect on the health of persons;

ii.the contaminant is known to occur or there is a substantial likelihood that the contaminant will occur in public water systems with a frequency and at levels of public health concern; and

iii.in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems.

Based on these SDWA criteria and currently available, AWWA supports EPA's proposed regulatory determination for perchlorate: Additionally, AWWA supports the EPA decision to issue a Health Advisory for perchlorate at the time of the final determination which provides important technical guidance to Federal agencies, State governments, and other public health officials.

The above conclusion is supported by independently developed assessments of both occurrence and exposure commissioned by AWWA. This research supports the finding that a national standard for perchlorate would not present a meaningful opportunity for health risk reduction for persons served by public water systems. The following provides a summary of our findings which are in the process of being submitted for peer-review.

EPA Comment Code: 6110

Comment: I recommend that EPA should not change its determination regarding the regulation of perchlorate. There is no need for every public water system in the US to test for a contaminant that only a few water sources contain. Let the states handle this on a case-by-case basis. I manage a public water system and we already spend thousands of dollars each year to test for contaminants that are not in our water and never have been in our water. I agree that we need to do as much as possible to ensure that our drinking water is safe, but the blanket regulations that govern drinking water are ineffective and facilitate wasteful spending of tax dollars.

Colby Goodliffe

Response: Please see the response to comment code 6110. The Agency analyzed occurrence data from the Unregulated Contaminant Monitoring Rule (UCMR), which is nationally representative, and found that perchlorate occurred in 26 states and 2 territories. Today's determination merely initiates the process of establishing a national primary drinking water regulation. It does not impose any requirements on public water systems. EPA will provide an opportunity to comment on the proposed regulation, along with health risk reduction and cost analysis, feasibility analysis, and other relevant analyses.

EPA Comment Code: 6110

Comment: Acknowledgements

The authors have collectively studied the toxicity of perchlorate since 1991 on behalf of US EPA and the nonprofit corporation Toxicology Excellence for Risk Assessment (TERA) at the request of the Perchlorate Study Group. Opinions expressed in this commentary, however, reflect solely those of the authors and not of any organization or other individual. Resources to support this technical commentary were provided by the Perchlorate Study Group, based in part on work supported by the developmental reserve fund of TERA.

Summary

We agree with EPA's decision to not regulate perchlorate on a national level at this time. Although the data do provide support for the conclusion that at sufficiently high doses, perchlorate may have adverse effects on sensitive groups within the US population, we agree with EPA's analysis that

perchlorate is not occurring in the public water supply at levels that cause concern for health risks. In particular, EPA's analysis of relative source contribution based on the FDA Total Diet Study and estimates of exposure based on the NHANES/UCR data give an excellent understanding of the potential for exposure for pregnant women, the sensitive population for perchlorate exposure.

Response: Please see the response to comment code 6110. As the federal register notice explains in greater detail, EPA has determined that, pursuant to the NRC's findings, infants and developing children are additional sensitive populations.

Comment: Conclusion

In this Federal Register notice, EPA is making a preliminary regulatory determination that a national primary drinking water rule is not necessary for perchlorate because a national primary drinking water regulation would not provide a meaningful opportunity to reduce health risk. In addition, EPA is announcing its plans to publish a Health Advisory, which will provide Federal, Regional, State, and Local public health officials with information regarding health risks posed from perchlorate-contaminated drinking water. Based on EPA's analysis of exposure data and relative source contribution, we agree that perchlorate is not occurring in the public water supply at levels that cause concern for health risks. However, we also recommend that EPA update its RfD prior to publishing a Health Advisory for the following reasons:

* Additional important data on pregnant women and their offspring have become available since the time of the development of the EPA's RfD in 2005, which necessitate a reconsideration of the existing value. This reconsideration is consistent with recommendations of the NAS (2005) in its report.

* The excellent relative source contribution evaluation of EPA, based on well supported and clearly described work of the FDA, necessitates a rethinking of the any RfD, since the underlying studies may not have measured perchlorate in the food of the human subjects.

* The 2005 "RfD" of the NAS does not follow the existing EPA method.

Tellez RT, Chacon PM, Gibbs J, Crump C, Abarca CR. 2005. Chronic Environmental Exposure To Perchlorate And Thyroid Function During Pregnancy And The Neonatal Period. THYROID: 15(9): 963-975.

Response: Please see the response to comment code 6110. In a NRC 2005 review of the state of the sciences regarding potential perchlorate adverse health effects and mode-of-action ("Health Implications of Perchlorate Ingestion", NRC (2005)), the NRC recommended that data from the Greer et al. (2002) human clinical study be used as the basis for deriving a perchlorate reference dose (RfD) (NRC 2005). From this Greer et al. (2002) human clinical study, the statistical no observed effect level (NOEL) for the perchlorate-induced inhibition of thyroid iodide uptake was determined to be 7.0 ug/kg, which corresponded to an iodide uptake inhibition of 1.8%. NRC concluded that the most health protective and scientifically valid approach to deriving a reference dose for perchlorate, was to base the perchlorate RfD on the inhibition of iodide uptake by the thyroid, and that iodide uptake inhibition, though not an adverse effect per se, is the most appropriate precursor event, and would precede any more severe adverse health effects of perchlorate exposure in humans. The NRC recommended basing the RfD on a precursor to an adverse effect rather than an adverse effect, per se. In this case, NRC used prevention of iodide uptake inhibition, a precursor to adverse thyroid effects, to establish a level at which no adverse effects would be anticipated in exposed populations. This approach is consistent with the Agency's policy on the use of precursor events when appropriate in establishing the critical effect upon which an RfD is based (U.S. EPA, 2002). The NRC recommended that EPA apply an uncertainty factor of 10 to this NOEL of 7.0 ug/kg for the perchlorate-induced inhibition of thyroid iodide uptake, to account for differences in sensitivity between healthy adults and the most sensitive sub-population, consisting of fetuses of pregnant women who might have hypothyroidism or iodide deficiency. EPA has also considered data derived from the Tellez et al. (2005) study. Blood serum perchlorate concentrations predicted through PBPK modeling from data from a study of school children in Chile (Tellez et al. 2005) were within the range of the measured concentrations, and the concentrations of perchlorate in breast milk predicted from the model were within two standard deviations of the measured concentrations. Therefore, PBPK modeling predictions of blood serum perchlorate concentrations were consistent with empirical results, and the predicted extent of iodide inhibition in the most sensitive population (the fetus), based in part on data from Tellez et al. (2005), was not found to be significant at EPA's RfD of 0.7 ug/kg/day.

EPA agrees that additional important data have become available since the RfD was derived in 2005. However, EPA has evaluated the new data and has decided to make the regulatory determination based upon the current RfD. EPA will continue to evaluate any new perchlorate data to determine its relevance to the regulatory determination in accordance with the SDWA.

Comment: P.O. Box 13222 Sacramento, CA 95813 November 18, 2008

Dr. Deborah L. Swackhamer, Chair Science Advisory Board Environmental Protection Agency

Dr. Joan Rose Chair SAB Drinking Water Committee Environmental Protection Agency

Dear Dr. Swackhamer and Dr. Rose:

We read with great interest your November 5, 2008 letter to Administrator Johnson concerning EPA's preliminary determination on a national drinking water standard for perchlorate. This letter states that "the SAB strongly believes that there must be a compelling scientific basis to support a determination not to regulate perchlorate..." We completely agree. Through the efforts of EPA's Office of Water, Office of Solid Waste and Emergency Response, and Office of Research and Development over the last decade, the Agency has developed this compelling scientific basis.

First, the overall scientific literature concerning perchlorate's potential effects on human health is extensive. There are very few compounds subject to EPA regulation that can rest on multiple pillars of scientific evidence, including animal studies in multiple species, occupational studies, environmental epidemiology studies, and human clinical trials. There are also very few compounds in which the mechanism of action is clear and occurs with welldefined, non-adverse precursors. And, there are very few compounds that have been subject to a rigorous and comprehensive National Academy of Sciences (NAS) review of the health effects.

As the NAS panel stated, unless these precursor effects occur, the subsequent adverse effects will not occur. To cite the NAS report,

The committee emphasizes that inhibition of iodide uptake by the thyroid has been the only consistently documented effect of perchlorate exposure in humans. The continuum of possible effects of iodide-uptake inhibition caused by perchlorate exposure is only proposed and has not been demonstrated in humans exposed to perchlorate (with the exception that in patients with hyperthyroidism doses of 200 mg daily or higher may reduce thyroid secretion). More important, the outcomes at the end of the continuum are not inevitable consequences of perchlorate exposure.[FN1: National Academy of Sciences, Health Implications of Perchlorate Ingestion, 2005, at 165 (pdf version). The noted dose of 200 mg/d is a conservative therapeutic value. When use of perchlorate to treat hyperthyroidism was common, doses of 400 mg/d were commonly prescribed, but were found to be slow to control thyrotoxicity and doses needed to be repeated 4 to 5 times/d, due to the rapid excretion of the drug. Although it still took an average of 9.4 weeks, doses of up to 2000 mg/d were given to reduce hyperthyroidism to a remission state (Wolff, 1998).]

Although no longer the drug of choice in the clinic for treating thyrotoxicosis, perchorate is still used medically. For example, perchlorate is used to treat amiodarone (an antiarrhythmetic agent) induced thyrotoxicosis.[FN2: 2 J. Wolff, Perchlorate and the Thyroid Gland, Pharmacol Rev. 1998; 50(1):89-105.] In other words, except for its deliberate medical use, exposure to perchlorate has not been shown to have caused reduced thyroid function in humans. In addition to the NAS conclusions, newer studies indicate that exposures to perchlorate at environmentally relevant levels have not been demonstrated to cause any effect on the health of persons.[FN3: See, Benjamin C. Blount, et al., Perchlorate Exposure of the US Population, 2001-2002, J Expos. Sci Envtl Epidem. 2006c; Benjamin C. Blount et al., Urinary Perchlorate and Thyroid Hormone Levels in Adolescent and Adult Men and Women Living in the United States, Envtl Health Perspect., 2006b, 1865-71; Rafael Tellez Tellez et al., Chronic Environmental Exposure to Perchlorate Through Drinking Water and Thyroid Function During Pregnancy and the Neonatal Period, Thyroid, 2005, 963-975; Yona Amitai et al., Gestational Exposure to High Perchlorate Concentrations in Drinking Water and Neonatal Thyroxine Levels, Thyroid, 2007, 843-850; Craig Steinmaus et al., Impact of Smoking and Thiocyanate on Perchlorate and Thyroid Hormone Associationsin the 2001-2002 National Health and Nutrition Examination Survey, Envtl Health Perspect, 2007, 1333-38.] The weight-of-evidence suggests that adverse effects do not occur following chronic exposures to perchlorate at doses much greater than the RfD.[FN4: See, Tellez et al., 2005; Amitai et al., 2007; Lewis E. Braverman et al., The Effect of Perchlorate, Thiocyanate, and Nitrate on Thyroid Function in Workers Exposed to Perchlorate Long-Term, J. Clin. Endocrinol. Metab., 2005, at 700.]

Second, this extensive scientific literature has undergone several major peer reviews. EPA convened peer review panels of its draft risk assessments in 1999 and 2002. The University of Nebraska Medical Center convened a State-of-the- Science Symposium and peer review in 2003. From October 2004 to January 2005, the NRC panel of 15 national experts held several meetings and solicited extensive public comment. While the SAB can contribute to the findings of these panels, EPA already has extensive, independent scientific analysis of perchlorate to underpin its final determination.

Response: Administrator Stephen Johnson replied to the SAB on January 9, 2009. The letter is available in EPA's docket ID No. EPA-HQ-OW-2009-0297 for this notice.

Water Docket Environmental Protection Agency 1200 Pennsylvania Avenue, NW Washington, DC

RE: Docket ID No. EPA-HQ-OW-2008-0068 Drinking Water: Preliminary Regulatory Determination on Perchlorate

The Public Services Department of the Town of Mooresville, North Carolina agrees with the Environmental Protection Agency's determination that a national primary drinking water regulation (NPDWR) for perchlorate would not present a meaningful opportunity for health risk reduction for persons served by public water systems.

Our determination is based on several factors including research studies submitted by the EPA, NAS/NRC and FDA as well as articles released by accredited organizations. Authorities concur exposure to perchlorate is not limited to public water sources but is also found in food products. Public water sources found with maximum levels of perchlorate affect a small population of the country and would be better managed at a local level. The results of testing by a third party laboratory in 2002 showed no significant level of perchlorate in the Town of Mooresville's drinking water supply. All test results were below the detection limit of 4u/l.

Should you have any questions, please do not hesitate to contact us.

Sincerely,

John C. Vest, P.E. Public Services Director

Response: EPA believes that regulating perchlorate in drinking water presents a meaningful opportunity for health risk reduction. EPA believes that regulating perchlorate in drinking water presents a meaningful opportunity for health risk reduction. This determination is based on the best available peer reviewed science and data collected in accordance with accepted methods related to perchlorate's occurrence in drinking water , the presence of perchlorate in foods and the potential health effects of exposure to perchlorate, and EPA's population exposure evaluation as described in more detail in the final regulatory determination.
Specifically, The Agency analyzed occurrence data from the Unregulated Contaminant Monitoring Rule (UCMR), which is nationally representative, and found that perchlorate occurred in 26 states and 2 territories affecting millions of people. EPA agrees that perchlorate contamination is widespread in foods; however, EPA does not believe that the widespread presence of perchlorate in food overrides the opportunity for public health risk reduction for persons served by PWSs with perchlorate contamination.

US Environmental Protection Agency Office of Water Docket (Mailcode 2822T) 1200 Pennsylvania Avenue, NW Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2008-0692. Comments on US EPA Preliminary Regulatory Determination on Perchlorate.

The undersigned representatives of the California agricultural industry are pleased to submit the following comments regarding US EPA's preliminary regulatory determination on perchlorate. California agriculture is a diverse and important sector of our economy. It is a $37 billion industry that produces over 350 different crop and livestock commodities and generates an estimated $100 billion in related economic activity. California agriculture accounts for approximately 7.5% of all employment and supports over a million on farm jobs. California agriculture is also the leading exporter of agricultural commodities, sending almost 20% of our agricultural production to foreign markets.

Based upon the available scientific studies as well as the available exposure and occurrence data, the undersigned support EPA's decision not to establish a national primary drinking water regulation for perchlorate. Both the US Food and Drug Administration's (FDA) food sampling data and total dietary survey, along with EPA's calculated relative source contribution reveal that total perchlorate exposure in the US population is well below established levels of human health concern, even for sensitive subpopulations.

Response: Please see response to comment code 6110. The Agency presented an extensive evaluation of dietary exposure to perchlorate in the October 2008 and August 2009 Federal Register notices. EPA has used this dietary exposure data to account for the relative source contribution (RSC) of perchlorate from food and derived potential alternative HRLs for 14 life stages using the RfD and life stage-specific exposure information in the August 9, 2009 Federal Register notice. These levels range from 1 ug/L to 47 ug/L. EPA also evaluated the populations exposed to perchlorate from both food and drinking water in the August 2009 Federal Register notice and the final regulatory determination. EPA recognizes that a drinking water regulation would not eliminate perchlorate exposure in drinking water but believes that the reduction in perchlorate exposure

presents a meaningful opportunity for health risk reduction for persons served by PWSs contaminated by perchlorate.

.

RE: Comments in Response to the EPA Notice, Drinking Water: Preliminary Regulatory Determination on Perchlorate [EPA-HQ-OW-2008-0068; FRL-8727-6] RIN 2040-ZA02

Dear Sir or Madam:

The Perchlorate Study Group (PSG) is pleased to submit comments in response to the above-captioned EPA regulatory proceeding.

Please note that there are two sets of comments.

1. Perchlorate and Human Health in 2008: The Implications of New Science for the EPA Preliminary Determination. The most important issues for consideration by the Agency relate to the state of the science. The unswerving focus of the PSG has been to analyze and make available the best available scientific information. The scientific comments were prepared by Intertox, a highly-respected firm with extensive experience in the scientific considerations relating to perchlorate.

The Intertox report concludes that the scientific evidence supports the Agency's decision not to establish a national primary drinking water standard for perchlorate, because "there is no meaningful opportunity for health risk reduction."

The most important source of scientific information on the human health issues relating to perchlorate is an extensive report undertaken by the National Academies of Science, released in 2005. The NAS report has been relied upon by the EPA in subsequent regulatory actions.

The Intertox scientific comments bring the scientific information up to date, examining studies published after the NAS report. The Intertox study, like the NAS study, does not recommend a level for EPA's possible adoption. The Intertox report finds that even with highly conservative assumptions, there would be "no significant health risk to the most sensitive individuals" at a level of at or below 15 parts per billion.

Response: Please see the response to comment code 6110.

I. INTRODUCTION

The Environmental Protection Agency (EPA) has released its preliminary regulatory determination on perchlorate for public comment. The EPA is required by the Safe Drinking Water Act (SDWA) to publish Maximum Contaminant Level Goals (MCLG) and national primary drinking water regulations (NPDWR) IF (emphasis added),

(a) the contaminant may have an adverse effect on the health of persons; (b) the contaminant is known to occur in public water systems with a frequency and at levels of public health concern; and

(c) in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems (73 FR 60264).

Based on these criteria, the EPA has presented their rationale in the determination not to set an NPDWR for perchlorate as it would not present "a meaningful opportunity for health risk reduction for persons served by public water systems." This decision was made based on the derivation of a Health Reference Level (HRL) for perchlorate and was calculated to be 15 ppb based on a relative source contribution (RSC) of 62% (73 FR 60276)..

Even a cursory review of the 50 years of perchlorate research shows that the weight of scientific evidence clearly supports EPA's decision.

The purpose of this document is to review the key scientific studies and how these studies support the EPA's findings in the proposed determination. We present a brief review of the National Research Council of the National Academy of Sciences (NRC) assessment and update key studies that have been added to the scientific literature.

Between 1997 and 2002, at least 13 toxicological studies of perchlorate, all using EPA protocols, were conducted in animals; these include pharmacokinetic studies, subchronic studies, developmental studies, immunotoxicology studies, and a multigenerational reproductive study. All studies were conducted over a range of doses and evaluated independently by EPA. Of the many results obtained from this work, the most sensitive target organ was the thyroid gland and its influence on the body. Studies of potential mutagenic effects were conducted but no such effects were found (U.S. EPA, 2002). During the same time period, there were several clinical exposure studies in humans and a number of epidemiologic and ecological studies, some in occupational settings and some in populations exposed to perchlorate via the community drinking-water supply.

[Text Box: The body of science supports the Agency's decision not to establish a national primary drinking water standard as there is no meaningful opportunity for health risk reduction.]

Response: Please see the response to comment code 6110.

EPA Comment ID: 21079
EPA Comment Code: 6110

Comment: IV. CONCLUSIONS

The results of this assessment demonstrate that the RfD continues to be a conservative and health-protective toxicity guideline value. As such, perchlorate concentrations in drinking water at or below the HRL proposed by EPA pose no significant health risk to the most sensitive individuals consuming water on a daily basis over a lifetime. Since the release of the RfD, additional studies have been conducted and continue to add to the scientific weight of evidence supporting the RfD (and HRL) as conservative estimates. The RfD and HRL include uncertainty spanning perhaps an order of magnitude, and estimate a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. The

EPA has further determined that perchlorate is not found in public water supplies at a frequency and a level that would cause public health concern. Based on this, the EPA has determined that there is not "a meaningful opportunity for health risk reduction for persons served by public water systems" by determining a NPDWR.

Response: Please see the response to comment code 6110. EPA estimates that at least 5.1 to 16.6 million people are served by PWSs, for which we have data, that have perchlorate contamination. EPA has determined that an NPDWR for perchlorate could reduce exposures for these populations to levels below the potential alternative HRLs that EPA has identified as levels of public health concern for perchlorate.
EPA believes that this perchlorate exposure reduction presents a meaningful opportunity for the reduction of health risks for persons served by PWSs.

This determination is based on the best available peer reviewed science and data collected in accordance with accepted methods related to perchlorate's occurrence in drinking water, the presence of perchlorate in foods and the potential health effects of exposure to perchlorate, and EPA's population exposure evaluation as described in more detail in the final regulatory determination.

Comment: US Environmental Protection Agency Office of Water Docket (Mailcode 2822T) 1200 Pennsylvania Avenue, NW Washington, DC 20460

November 10, 2008

Re: Comments in Response to EPA Notice Drinking Water: Preliminary Regulatory Determination on Perchlorate [EPA-HQ-OW-2008-0692; FRL-8727-6].

The Perchlorate Study Group (PSG) is pleased to submit comments to the Environmental Protection Agency (EPA) on Docket ID No. EPA-HQ-OW-2008-0692, entitled Drinking Water: Preliminary Regulatory Determination on Perchlorate. As manufacturers and users of perchlorate, the PSG is committed to ensuring that the best available science is provided in public debate and applied in the subsequent setting of regulatory standards. The member companies of the PSG include Aerojet, American Pacific Corporation (AMPAC), Alliant Techsystems (ATK), and Tronox.

For over ten years, the PSG has worked cooperatively and effectively with the US Environmental Protection Agency (EPA) and other federal agencies, state governments, and water purveyors to:

* increase scientific and medical understanding of perchlorate's possible effects on human health; and,

* assess the level of perchlorate in drinking water that is expected to pose no adverse effects to human health.

We therefore appreciate this opportunity to submit these comments relating to EPA's preliminary determination.

I. The EPA's Proposed Determination is Backed by the Best Science and the Statute

The PSG agrees with EPA's preliminary determination that a Federal drinking water regulation would not meet the SDWA criteria and that EPA has ample justification for this determination. EPA has an extraordinary wealth of comprehensive, authoritative scientific information relating to perchlorate's health effects, supplemented by extensive occurrence and exposure data. The Agency is therefore exceptionally well-positioned to issue a well-considered regulatory determination. The best available scientific data supports a determination under the Safe Drinking Water Act (SDWA) that public water systems do not present a meaningful opportunity for risk reduction.

Comment: Second, EPA has ample scientific and technical data to make a final determination on or before the planned date of December 2008. As noted in the attached scientific summary, perchlorate is one of the most well-studied chemicals with detailed information on the mechanism of action, dose-response, and health effects. This issue also is not new. EPA released its first draft risk assessment on perchlorate in 1998, followed by a second in 2002. The 2005 NAS report was a comprehensive review of the science. The animal and human studies that have been published since the NAS report reduce the uncertainty and reinforce the NAS panel's finding that there will not be any adverse health effects from perchlorate at environmentally-relevant concentrations.

New studies published since the NAS report increase the weight of evidence that the current RfD protects human health including the most sensitive members of our population. In addition, testimony by Congressional members and witnesses alike have discussed the lengthy amount of time that EPA has spent studying the health effects, urging the agency to issue a determination as soon as practicable. We join them in urging EPA to issue the final determination promptly.

Perchlorate Supplemental Request Comments by South Dakota Department of Environment and Natural Resources (DENR)

General Comments:

- The South Dakota Department of Environment and Natural Resources (DENR) supports EPA's preliminary decision to not regulate Perchlorate, and finds no reason now to alter that decision. Based on the information obtained from the contaminant candidate list and Unregulated

Contaminant Monitoring processes used by EPA to obtain occurrence data on unregulated contaminates, Perchlorate is not a drinking water issue in South Dakota. Consequently, South Dakota does not support EPA establishing a new national regulation for Perchlorate. Such a new rule will become another regulatory burden for our drinking water systems, but it would have no positive health effects or benefits for their customers.

Response: Please see the response to comment code 6110.

Comment: The PBPK modeling is useful in demonstrating that all identified lifestages are protected at the RfD level, and especially under the current HAL of 15 ppb perchlorate in drinking water as they are within the 10x intraspecies factor. The alternative methods of exposure assessment are informative but do not show that any deviation from EPA's typical risk assessment based on a 70 kg adult consuming two liters of water is warranted. As the occurrence of perchlorate in water supplies is sporadic and geographically discreet, the Agency has not provided sufficient information or explanation to justify using Bayesian analyses of water occurrence data. EPA has sufficient information to determine that perchlorate should not be regulated as a drinking water contaminant under the Safe Drinking Water Act and should maintain a recommended health advisory limit of 15 ppb.

Response: Please see the response to comment code 6110. After further consideration of the peer review and public comments, EPA concludes that the PBPK modeling analysis, in the context of the perchlorate regulatory determination, is useful in examining which life stages are most susceptible to the effects of perchlorate. For example, the model indicates that a fetus may be seven times more sensitive to the effects of perchlorate than a pregnant woman. The model also allows for the estimation of the concentration of perchlorate in breast milk (thus breast-fed infant exposure) at various maternal perchlorate exposure levels. However, because of the stated limitations, EPA has decided the model does not directly bear on the current decision regarding the need for a NPDWR

for perchlorate. EPA is continuing to evaluate whether the model could be used in setting a NPDWR for perchlorate.

EPA believes that perchlorate contamination in drinking water does not occur sporadically. The Agency analyzed occurrence data from the Unregulated Contaminant Monitoring Rule (UCMR), which is nationally representative, and found that perchlorate occurred in 26 states and 2 territories.

EPA continues to evaluate the utility of the Bayesian model(s) in the development of a NPDWR for perchlorate.

The Environmental Protection Agency (EPA) has sufficient information to make a regulatory determination concerning perchlorate under the Safe Drinking Water Act (SDWA) - perchlorate does not meet the three criteria necessary for regulation - therefore, the Administrator can determine that the EPA should maintain its guidance for a Health Advisory Limit (HAL) at 15 parts per billion (ppb) in drinking water and can decide not to regulate perchlorate under the SDWA. The Agency continues to waste public resources and time based on ill- informed critiques of the National Research Council (NRC) 2005 findings on perchlorate.

Comment: Conclusion

Based upon the best available scientific evidence, including exposure and occurrence data developed since the National Academy of Sciences issued its findings in January, 2005, the undersigned conclude that the regulatory thresholds contemplated in EPA's above referenced notice are not scientifically justified and are substantially more stringent than necessary to ensure protection of public health. Moreover, the US Food and Drug Administration's (FDA) food sampling data and total dietary survey, and the relative source contribution calculated by USEPA for its 2008 preliminary regulatory determination demonstrate conclusively that total perchlorate exposure in the US population is well below established levels of human health concern for both the general public and sensitive subpopulations.

For the reasons articulated above, the California agricultural industry encourages USEPA to act on its October 10, 2008 preliminary regulatory determination for perchlorate, which the weight of scientific evidence demonstrates to be highly health protective. We appreciate USEPA's consideration of our comments and we remain committed to working with USEPA, USDA and FDA to preserve the safety and integrity of our products and their contribution to balanced, healthy diets.

EPA Comment Code: 6110

Comment: Introduction

These comments are provided in further support of EPA's preliminary determination that establishment of a perchlorate drinking water standard is not merited, and in reference to comments already posted by Jonathan Borak on September 21st under reference EPA-HQ-OW-2009-0297-0209.1. Mr. Borak's comments refer primarily to the Blount, et al., 2006 study regarding the association of low background levels of perchlorate with thyroid hormone levels. Notwithstanding the many inconsistencies and contradictions in this study as noted by Mr. Borak and others, it is

clear in reviewing other comments submitted under Docket EPA-HQ-OW-2009-0297, that the Blount study is still being heavily relied upon by supporters of perchlorate regulation, who point to this study as proof of the effect of low background levels of perchlorate on thyroid function.

Response: Please see the response to comment code 6110. EPA did consider the data presented in the Blount et al., 2006 study as well as other information on perchlorate exposure. EPA will consider the best available science and information as EPA develops the perchlorate regulation.

U.S. Environmental Protection Agency Office of Water Docket (Mailcode 2822T) 1200 Pennsylvania Ave. NW Washington, DC 20460

RE: Drinking Water: Perchlorate Supplemental Request for Comments Docket EPA-HQ- OW-2009-0297

The American Water Works Association appreciates the opportunity to comment on the supplemental request for comments regarding perchlorate as detailed in the August 3, 2009 Federal Register notice (74 FR 41883). AWWA is an international, nonprofit, scientific and educational society dedicated to the improvement of drinking water quality and supply. Founded in 1881, the Association is the largest organization of water supply professionals in the world. Our 57,000 members represent the full spectrum of the drinking water community: treatment plant operators and managers, environmental advocates, engineers, scientists, academicians, and others who hold a genuine interest in water supply and public health. Our membership includes more than 4,700 utilities that supply roughly 80 percent of the nation's drinking water. Based on this broad membership base, these comments should be considered as representative of the drinking water community in general.

These comments represent a restatement of the position submitted to the Agency in response to preliminary regulatory determination for perchlorate as detailed in the October 10, 2008 Federal Register notice (73 FR 60262). Given the weight of evidence available at that time and AWWA's independent assessment of occurrence and exposure we concurred with Agency's preliminary determination that regulation of perchlorate would not present "a meaningful opportunity for health risk reduction for persons served by public water systems." We continue to support that preliminary determination. **Response:** Please see the response to comment code 6110.

EPA Comment ID: 28857
EPA Comment Code: 6110

Comment: Conclusion

AWWA believes that the Agency's originally proposed decision not to regulate perchlorate is supported by the criteria established in the SDWA. The primary public health issue - as stated by the NRC and others including the Agency's Inspector General [FN22: Wilson, M. 2008. Scientific Analysis of Perchlorate. US Environmental Protection Agency, Office of Inspector General:Washington DC. Available at http://www.epa.gov/oigearth/reports/2009/20081230-2008-0010.pdf] - is iodine deficiency. The SDWA is not an effective means or "tool" to manage a public health issue dominated by dietary issues. The public's exposure to all sources of goitrogens due to extensive contributions from other sources as demonstrated by the FDA food market assessment support the findings that regulation of drinking water would not have a meaningful impact on changing the nation's level of iodine deficiency. A precautionary approach is not justified by the available public health data that provides no indication of epidemic cretinism, goiter, or hypothyroidism, even given the loading of other goitrogens that far exceed potential contribution from perchlorate from all sources. A risk management approach that seeks to extract 100 percent of the risk reduction value from the smallest possible source is not only ineffective, but is a disservice to the mission of seeking the greatest protection of public health. The Agency should use the findings of this assessment to support a collaborative effort with the Department of Health and Human Services and Department of Agriculture to develop outreach materials that communicate the importance of proper dietary levels of iodine, specifically targeting sensitive subpopulations. Attempts have been made in the past to ensure the public received appropriate iodine levels.[FN23: Medicine: Pass the iodized salt, in Time 1949, 19 September. Available at http://www.time.com/time/magazine/article/0,9171,800702,00.html] AWWA believes that remains a better approach for addressing the problem of iodine deficiency, instead of using the Safe Drinking Water Act to address this issue

AWWA appreciates the opportunity to comment on these important drinking water issues. If you have any questions about these comments, please feel to call Kevin Morley or me in our Washington Office at 202-628-8303.

Sincerely, Tom Curtis Deputy Executive Director-Government Affairs

cc: Peter Silva, OW Cynthia Doughtery, OGWDW Eric Burneson, OGWDW

Response: Please see the response to comment code 6110. EPA agrees that promoting iodide nutrition is good public health policy that has a role in reducing the adverse effects associated with exposure to perchlorate. However, the Agency is required to undertake the development of a national primary drinking water regulation if the provisions under section 1412(b)(1) of SDWA are satisfied. That is, if the three legislative criteria are met, EPA must undertake the development of a NPDWR. EPA has determined that the three criteria are met for perchlorate for the reasons outlined in today's federal register notice.

EPA Comment ID: 28875
EPA Comment Code: 6110

Comment: EPA, based on a scientific assessment of the literature in 2008, concluded that federal regulation of perchlorate in drinking water is unwarranted. More than 50 years of scientific research and guidelines support the Agency's position.

I. INTRODUCTION

On August 19, 2009, the Environmental Protection Agency (EPA) issued a Federal Register (FR) notice requesting comments on additional approaches to analyzing data related to EPA's perchlorate regulatory determination (the Notice; U.S. EPA, 2009b). The Notice states that "these additional comments are sought in an effort to ensure consideration of all the potential options for evaluating whether there is a meaningful opportunity for human health risk reduction of perchlorate through a national primary drinking water rule." This document responds to EPA's request for comments on behalf of the Perchlorate Study Group (PSG).[FN1: The PSG member companies include Aerojet General Corporation, American Pacific Corporation, ATK, and Lockheed Martin Corporation.]

EPA is required by the Safe Drinking Water Act (SDWA) to publish Maximum Contaminant Level Goals (MCLGs) and National Primary Drinking Water Regulations (NPDWR) if all the following statutory requirements are met:

(a) the contaminant may have an adverse effect on the health of persons;

(b) the contaminant is known to occur in public water systems with a frequency and at levels of public health concern; and

(c) in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems (U.S. EPA, 1996).

EPA's statutory criteria for setting a standard are unmet in this case. At exposure levels anticipated under the drinking water program, the toxicological literature for perchlorate has demonstrated no adverse effect on human health. Second, data from EPA's first cycle of the Unregulated Contaminant Monitoring Rule (UCMR1) demonstrates that perchlorate does not consistently occur in public water systems at levels that may cause adverse effects in humans. Lastly, because the first two requirements are not met, there is no meaningful opportunity for health risk reduction, the third requirement.

In 2008, EPA concluded that perchlorate did not meet the SDWA requirements and released its preliminary regulatory determination on perchlorate for public comment (U.S. EPA, 2008a). EPA decided not to set an NPDWR for perchlorate as it would not present "a meaningful opportunity for health risk reduction for persons served by public water systems." This decision was based on a Health Reference Level (HRL) for perchlorate in drinking water of 15 ppb, calculated based on an assumed relative source contribution (RSC) for drinking water of 62% of the reference dose (RfD) (U.S. EPA, 2008a).

Data on perchlorate exposure in humans support EPA's preliminary regulatory determination. Any chemical at a sufficient dose will cause an adverse effect. Since the inception of EPA's evaluation of perchlorate and its interim guidance, no evidence of adverse effects from exposure to perchlorate at environmental levels in the U.S. has been presented.[FN2: In 1992, EPA began to address "...concerns about the potential human health effects of perchlorate discovered in drinking water..." and the EPA Superfund Technical Support Center proposed a "provisional" RfD for perchlorate of 0.0001 mg/kg-d which translates to a drinking water equivalent level (DWEL) of 4 ppb (Dollarhide, 1992). In 1995 the provisional RfD was revised by EPA and the National Center for Environmental Assessment (NCEA) to a range that translates from a DWEL of 4 to 18 ppb (Dollarhide, 1995). EPA released a document detailing the derivation of a revised provisional RfD for perchlorate (U.S. EPA, 1998a). In this analysis, EPA focused on potential secondary effects of perchlorate exposure in the developing organism. In 1999, EPA issued was what is referred to as the "1999 Interim Guidance" (Noonan, 1999). EPA states, "...the Office of Research and Development (ORD) recommends that the Agency's risk assessors and risk managers continue to use the standing provisional RfD range of 0.0001 to 0.0005 mg/kg-d [4 to 18 ppb equivalent] for perchlorate-related assessment activities." At the same time, the EPA's Office of Water added perchlorate to the Contaminant Candidate List (CCL) and perchlorate was added to the UCMR (U.S. EPA, 1999). In 2003, EPA's Assistant Administrator issued a Memorandum stating, "...we are re-affirming this guidance with an added suggestion to carefully consider the low end of the provisional 4-18 ppb range."]

50 years of perchlorate toxicological research shows that the scientific weight- of-evidence decidedly supports EPA's preliminary regulatory determination on perchlorate.

A review of the 50 years of perchlorate toxicological research shows that the weight of scientific evidence decidedly supports EPA's preliminary regulatory determination on perchlorate. Furthermore, EPA requested manufacturers and users to fund specific scientific studies on the health effects of perchlorate. As a result, at least 12 animal studies that cover reproductive and developmental toxicity, carcinogenicity, endocrine effects, and other specific toxicological endpoints were funded and conducted.[FN3: For example, the following animal studies were required by EPA to fill data gaps: Argus Research Laboratories, Inc., 1998; Argus Research Laboratories, Inc., 1999; Kiel et al., 1998, 1999; Argus Research Laboratories, Inc., 2001; Primedica, 2001; Bekkedahl et al., 2000; BRT, 2000a, 2000b; Siglin et al., 2000; York et al., 2001a, 2001b.] The results of the studies were transmitted directly to EPA for analysis and without review from industry.

Response: Please see the response to comment code 6110.

Commenter Name:
Commenter Organization: Intertox, Inc.
EPA Document ID: EPA-HQ-OW-2009-0297-0662
EPA Comment ID: 28905
EPA Comment Code: 6110

Comment: In summary, EPA's existing, scientifically based RfD remains a conservative, healthprotective toxicity guideline value. Perchlorate concentrations in drinking water at or below the 15 ppb HRL set by EPA, along with its existing, preliminary determination, pose no significant health risk, even to the most sensitive individuals consuming water on a daily basis over a lifetime.

Finally, the best available science establishes that none of the three requirements of the SDWA are met; therefore, there is no scientific justification to regulate perchlorate under this statute.

Table 2. Alternative HRLs based on corrected water intake rates. [see PDF docket ID EPA-HQ-OW-2009-0297-0662]

Table 3. Comparison of daily water ingestion to blood volume. [see PDF docket ID EPA-HQ-OW-2009-0297-0662]

Response: Please see the response to comment code 6110. EPA continues to support the RfD. EPA has determined that perchlorate meets the criteria for regulating a contaminant in Section 1412(b)(1)(A) of SDWA. As previously discussed in this notice, perchlorate may have an adverse effect on the health of persons and perchlorate is known to occur or there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern. Moreover, in light of the discussion in this notice and the information available at this time, the Administrator finds that regulation of perchlorate in drinking water systems presents a meaningful opportunity for health risk reduction for persons served by public water systems. Therefore, EPA will initiate the process of proposing a NPDWR for perchlorate.

EPA Comment Code: 6120 Comments urging EPA to regulate perchlorate

Response to Code 6120: EPA has determined that the following three SDWA criteria for regulatory determination have been met for perchlorate: (1) It may have an adverse effect on the health of persons; (2) It is known to occur or there is a substantial likelihood that perchlorate will occur with a frequency and at levels of public health concern in public water systems; and (3) In the sole judgment of the Administrator, regulation of perchlorate presents a meaningful opportunity for health risk reduction for persons served by public water systems. EPA is initiating the development of a proposed NPDWR for perchlorate. EPA intends to publish a proposed regulation and analyses required by SDWA for public review and comment within 24 months of this notice. EPA will consider the public comments and expects to promulgate a final regulation within 18 months of the proposal

EPA Comment Code: 6120

Comment: Please regulate the contaminate perchlorate in out drinking water here in AZ to at least the same standards as CA has of 6ppb. The truth of the matter is that the standard should be set as 2 or 3 ppb, but I know this will never happen as long as the DEPT of Defense interferes with this matter and scientific data is tampered with. This current deregulation costs our country millions with medical problems associated with perchlorate and what this does to our children.

Response: See response to comment code 6120.

Comment: As a layman with a little background in chemistry the word "perchlorate" scares me, especially since we are advising people to restrict their use of such cleaners as Chlorox for home use. Perchlorate presents an excess of chlorine to rocket fuel as an oxidizer, but we do not need or want that in our drinking water.

Comment: When I recently moved from California to Phoenix Arizona I learned that the local water supply is contaminated with Perchlorate. The EPA had the responsibility to prevent such contamination at the time it was occurring. Since that did not happen it must protect the public health by controlling the legal limit. Raising the limit does not make any sense given the onslaught of contaminants assaulting the public from all angles. If anything, it should be lowered (since cleanup is not possible).

Please at least do not raise the legal limit.

Melissa Mandel

Comment: Perchlorate is a dangerous chemical and harmful to women and children. It should actually be banned as it is now showing up in milk and lettuce across the nation.

Not strictly regulating this harmful chemical in our drinking water is totally unacceptable.

It is clear the the EPA has come under the control of industry. This outrageous decision to allow more and more perchlorate contaminants to be considered acceptable in our water is just too much.

EPA must remember why the taxpayers pay the salaries of those who work there. The American people and the future generations must be protected from these kinds of exposures.

The Safe Water Drinking Act must be honored and EPA must act in good faith on behalf of the public.

You are killing the people.

Comment: Docket ID No. EPA-HQ-OW- 2008-0068 Drinking Water: Preliminary Regulatory Determination on Perchlorate I recently moved to Phoenix Arizona and learned upon arrival that Perchlorate is a risk factor in the local water supply due to contamination of the ground water. Since the EPA did not protect this vital resource for our health and safety at the time the damage was done, it should at least protect us now and into the future. Raising the legal limit protects the interests of polluters, not the public health. Please do not approve such a change in the regulation of this contaminant. M. Mandel

Comment: Return regulations to safe levels of perchlorate in water supply and throughout the food chain.

I have high levels I am now experiencing thyroid problems, I face removal of part of my thyroid as the only means to mitigate the signs and symptoms of my thyroid condition.

I see a direct correlation to excess ive levels of perchlorate being allowing into our water supply and food chain.

It is your vested responsibility to oversee environmental conditions to prevent the American people from diseases and conditions detrimental to their health and well being and this issue must be seriously addressed in good faith or you are failing in your responsibilities to citizens. Thank you

Comment: I am an individual, living in Palo Alto, CA Perchlorate is KNOWN to be unhealthy. Therefore I consider it IMPERATIVE that regulations be made to limit it. Actually, if we were to use the Precautionary Principle, we would not allow ANY AMOUNT in our water, until it could be proven that some amount was NOT unhealthy/damaging. However since we don't operate that way, and since without regulations, those who produce/ use perchlorate won't bother to be careful, we need a specified limit.

Response: See response to comment code 6120.

Comment: Concerning: EPA-HQ-OW-2008-0692 Docket Title Drinking Water: Preliminary Regulatory Determination on Perchlorate Docket Type Nonrulemaking Document ID EPA-HQ-OW-2008-0692-0001

October 15, 2008

Dear Reader,

I am a fourth year biology major at the University of Chicago and am deeply concerned about the current dangerously high perchlorate allowance. I recommend that regulations be made immediately limiting the industrial output of perchlorate and perchlorate related compounds. Perchlorate interferes with iodide uptake in the thyroid, and the news of significant levels being found in breast milk and elsewhere is disturbing. If a woman cannot safely breastfeed her child, we are in dire straights indeed.

EPA Comment Code: 6120

Comment: As a concerned citizen, I urge you to set a cautious standard for regulating perchlorate in drinking water.

I worked at Rocketdyne in Canoga Park in the late 1960's, where I began having thyroid problems for the first time and have subsequently developed autoimmune issues and chemical sensitivities. Please consider that the human immune system can tolerate only a finite amount of toxicity from all sources before it begins to break down. Perchlorate may be only one of many hazards in our water system but that does not make it insignificant enough to overlook.

The role of the Environmental Protection Agency is to protect us from harmful substances. Please exercise diligence in carrying out your role.

Response: See response to comment code 6120.

Comment: I am extremely concerned about the increased risk of exposure to harmful toxins such as perchlorate in tap water. This is a significant public health issue, putting young children, pregnant women, unborn children at risk. I urge you to re-examine your standards of acceptance regarding perchlorate. I thank you for considering my comment and rethinking policies.

Sincerely, Elizabeth Sheehan

Comment: I am dismayed that the EPA has refused to set an appropriate drinking water standard for perchlorate. This rocket fuel chemical has been linked to thyroid problems in pregnant women, newborns and young children. The maximum safe level is now 15 times higher than what the EPA declared safe in 2002. The new standard puts 20 to 40 million of us at risk. I think the EPA should be doing a better job of protecting us; that is what it was set up to do, and that is what we taxpayers are paying for the EPA to do.

Response: See response to comment code 6120.

Comment: The EPA exists to PROTECT Americans from the predators that manipulate science; PROTECT our children from the chemicals that do them harm (indeed permanent damage). Career scientists at the EPA know the right thing to do on this issue. I beg you to have the courage to do the right thing. Leave politicians and well-funded lobbyists out of this decision.

Please, provide tight regulation on perchlorate.

While you're at it, demand that the polluters pay to clean up the mess they've made -- we all know they've taken an obscene amount of our tax dollars as profit!

Sincerely, Mary Beth Sullivan 212 Centre Street Bath, Maine 04530 207 443 9502 mbsull@mindspring.com

Response: See response to comment code 6120. Requiring polluter payment is outside the scope of this rule; no response is necessary.

Comment: I understand that the EPA is considering raising the bar on "safe" levels of byproducts of rocket fuel in our drinking water. This is the kind of politically driven lack of concern for citizen health that we've come to expect from our government.

I object to this agency playing cancer roulette with my health and the health of the nation.

Until and unless each water contaminant is tested for safety by the Ames test or another reputable test you should NOT deem any levels of rocket fuel or its byproducts as safe in food water or drink.

Let's see some concern for the public good in your policies. Judith Weiss

Comment: This is a Public Comment Regarding EPA's refusal to regulate Perchlorate under the Safe Water Drinking Act (Docket ID EPA-HQ-OW-2008-0692):

At least six of my friends and family members have serious thyroid conditions, probably due to environmental exposures. This is epidemic, and it's no time to allow MORE perchlorate in drinking water, as it is something already known to help cause thyroid problems in pregnant women, newborns and young children.

You know how widespread perchlorate exposure is now in America. Setting a standard for it is a real step toward health risk reduction. Choosing not to regulate is choosing more disease, particularly for children.

Comment: This is written by Dorothea Leicher, at 2303 Delancey Pl, Philadelphia, PA, 19103, as a Public Comment regarding EPA's refusal to regulate Perchlorate under the Safe Water Drinking Act (Docker ID EPA-HQ-OW-2008-0692)

Perchlorate has been linked to thyroid problems in pregnant women, newborns and young children. As mother, this kind of risk to my daughter and her children is of great concern.

Perchlorate is found in the drinking water of 35 states, so that regulating it would provide a significant protection for the public.

Safe drinking water is an extremely important asset, and one that we will have to rely on increasingly as water becomes scarcer. the trust in tap water has already been assaulted by the bottled water industry and it is especially important now do everything to protect this public resource in the spirit of the Safe Water Drinking Act. Thank you for your time and attention.

EPA Comment Code: 6120

Comment: Perchlorate toxicity is proven beyond doubt. Why is there a question about its' regulation? It is ridiculous to poison people on purpose although the U.S. chemical industry has been doing so for half a century. Most of the cancers, thyroid problems, and birth defects seem related to the chemical industry and the lack of proper regulation from the EPA. If the EPA cannot do better, they should start over with a new agency that can protect us and close this one down.

Response: See response to comment code 6120.

EPA Comment ID: 19881
EPA Comment Code: 6120

Comment: Do not allow more Perchlorate in our drinking water! Our water continues to degrade in quality - in part by various pollutants which are virtually impossible to study in the combinations they'll actually appear in. These combinations are virtually impossible to study due to their large numbers, but evidence so far indicates that the total effect of these pollutants is worse than the sum of effects of the separate pollutants.

Clean water is critical for life - and it's far cheaper and more sensible to keep the water clean rather than to clean it up after it's polluted.

Response: See response to comment code 6120.

EPA Comment ID: 19901
EPA Comment Code: 6120

Comment: My wife (Mary Duplisea-Palmer) and I (James R. Palmer) live at 66 Albert Pt. in Stetson, ME. This is our public comment regarding EPA's refusal to regulate Perchlorate under the Safe Drinking Water Act: Please continue to regulate this chemical according to the standard that was in place before this proposed change. Clean drinking water is so important to life, and, unfortunately, humankind has pollutted it too much already. Even using EPA's data, this chemical is wide-spread already. Continue to do the job your agency was created to do.

Response: Perchlorate is not regulated in drinking water. See response to comment code 6120.

Comment: I am writing to urge the EPA to control the contamination of our drinking water and, by extension, our food supply with regard to perchlorate. The following is medical information regarding this toxic chemical, per the EPA itself:

PERCHLORATE

The EPA has established an official reference dose (RfD) of 0.0007 mg/kg/day of perchlorate. This level is consistent with the recommended reference dose included in the National Academy of Science's January 2005 report. A reference dose is a scientific estimate of a daily exposure level that is not expected to cause adverse health effects in humans. Risk information about perchlorate and perchlorate salt.

Perchlorate is a man-made anion commonly associated with the solid salts of ammonium, potassium, and sodium. Ammonium perchlorate is the mostly widely used perchlorate compound. It has also been found to occur naturally in certain highly arid environments. These salts are highly soluble in water, and because perchlorate adheres poorly to mineral surfaces and organic material, it can be very mobile in surface and subsurface aqueous systems. Also, since it is relatively inert in typical groundwater and surface water conditions, perchlorate contamination may persist for extended periods of time.

Perchlorate interferes with iodide uptake into the thyroid gland. Because iodide is an essential component of thyroid hormones, perchlorate disrupts how the thyroid functions. In adults, the

thyroid helps to regulate the metabolism. In children, the thyroid plays a major role in proper development, in addition to metabolism. Impairment of thyroid function in pregnant mothers may impact the fetus and result in such effects as changes in behavior, delayed development and decreased learning capability. Drinking water contaminated with perchlorate is the most likely way that perchlorate can be ingested.

Recent studies conducted by the U.S. Department of Agriculture (Nov. 2004) and the Environmental Working Group (Apr. 2003) have detected perchlorate in samples of lettuce in California. Several other studies also detected perchlorate in milk samples taken from California and Texas. Additional studies of perchlorate uptake in food crops are currently being conducted by the U.S. Food and Drug Administration.

Production of ammonium perchlorate first began in the United States in the mid- 1940s, primarily for use by the U.S. military. The most common uses for ammonium perchlorate are in explosives and rocket propellants, which have been widely used in military munitions items, such as mortars, grenades and flares and solid fuel rocket. Based on production data from two perchlorate manufacturers, it is estimated that 90 percent of perchlorate compounds are manufactured for use in defense activities and the aerospace industry. While occurring most frequently at domestic Air Force installations, ammonium perchlorate has been detected at Army and Navy sites too. The National Aeronautics and Space Administration (NASA) and Department of Energy (DOE) also have a small number of facilities with perchlorate (specific information on known perchlorate releases in the U.S. (XLS) (PDF, 7 pages, 515KB), as of September 23, 2004). In addition, ammonium perchlorate and the other perchlorate salts have been or are used in a wide range of applications, including pyrotechnics and fireworks, blasting agents, solid rocket fuel, matches, lubricating oils, nuclear reactors, air bags and certain types of fertilizers. Improper storage and/or disposal related to the uses mentioned above are the most typical route for perchlorate to enter into the environment.

The EPA has been working with states, federal agencies, tribes, water suppliers and the private sector for several years to address perchlorate. In 1998, EPA released an Interim Assessment Guidance for Perchlorate (PDF, 4 pages, 224KB), which was then subject to peer review in 1999. The external review draft of the revised document "Perchlorate Environmental Contamination: Toxicological Review and Risk Characterization," (November, 2002) responds to those recommendations emanating from the peer review.

The National Research Council of the National Academies published its technical review of the Health Implications of Perchlorate Ingestion in January 2005. From this review, EPA has established an official reference dose of 0.0007 mg/kg/day of perchlorate. This level is consistent with the recommended reference dose included in the National Academy of Science's report. A reference dose is a scientific estimate of a daily exposure level that is not expected to cause adverse health effects in humans.

Thank you for your attention to this matter. As a practicing OB/Gyn, I am intimately concerned with your actions, on behalf of my patients and their children, both born and unborn.

Comment: I am VERY sure that the United States needs very specific regulations on the amount of perchlorate allowed in public drinking water. Strict Regulations.

The American public expect to be protected by the EPA and their government, not subject to policies that make it easy for pollution to remain in their

water and polluters to go unpunished. We need to change jet fuel if it pollutes water sources.

Do not let Americans down by allowing pollution that may cause Thyriod problems to remain in our water. There are at least 5 people i can name who have thryriod issues, many living in our tiny little town that is too small to have a post office.

my husband was diagnosed 2 months ago.

This is a VERY serious issue. Do not allow corporations to continue as they are, just because it's easy to avoid rocking the boat.

Thank you for your time and attention to this matter.

Comment: As a public health physician and a Pediatrician, I am very concerned about potential hazards of perchlorate in drinking water. There appears to be ample evidence of potential thyroid disease in newborns and young children.

Please strongly consider setting a standard for maximal allowable perchlorate levels in drinking water.

Thank you for your consideration.

Response: See response to comment code 6120.

Comment: Even if the perchlorate itself posed no apparent harm, which I believe it does, there have been no adequate studies of how iut interacts with othere chemicals or how sensitive individuals react to it. Additionally, how can the EPA or any group force American citizens to expose themselves to chemicals they believe they should not have in their systems?

Response: This is not a comment, a response is not necessary.

Comment: I am writing to express my concern regarding the EPA's failure to regulate perchorate, as well as the proposed reference level. The citizens of the USA neeed their health protected from this toxin in our water. The health of our children need this protection. Thyroid disease has become too common and this autoimmune disease affects ones entire health. It is not a simple disease. It is not diaganosed and controlled easily as some seem to think. I request that the EPA take time for a complete and through evaluation, review the ever-changing scientific findings permitting the community time to evaluate and comment on the findings. Please do not rush a decision, one that could adversily affect the women and children of this great nation.

Response: See response to comment code 6120.

EPA Comment Code: 6120

Comment: Given the nature of the epidemic of thyroid dysfunction, and the increased health cost of treatment of such dysfunction, it is essential to set new, regulatory levels of Perchlorate in Drinking water to absolute lowest levels, with intention to eliminate sources of additional contamination in an urgent and immediate timely approach to safeguard further risk to public exposure.

Further, all public schools must be equipped with appropriate filters on drinking water taps immediately.

Further, all public facilities = hospitals, restaurants, should be strongly advised to obtain, through tax relief measures, safe and reliable filters for all tap water sources.

The public has the right to be protected. The cost of prevention far out weighs the cost of treatment.

Response: See response to comment code 6120.

Eric Burneson Office of Ground Water and Drinking Water Standards and Risk Management U.S. Environmental Protection Agency

Dear Sir:

We are concerned that the EPA's failure to regulate perchlorate, as well as its unprotective proposed health reference level, will adversely affect the health and development of hundreds of thousands, perhaps millions of American children. In addition, expecting mothers will run the risk of permanently damaging the development of their unborn children. Not only will unborn children be affected, but the elderly population as well. Elderly people with a history of medical conditions will have a difficult time fighting off the effects that perchlorate may have.

Response: See response to comment code 6120.

Comment: Docket # EPA-HQ-OW-2008-0692 Environmental Protection Agency Mailcode: 2822T, 1200 Pennsylvania Ave., NW Washington, 20460

Dear Administrator Johnson and EPA staff,

I urge you to set a drinking water standard for perchlorate that will protect pregnant women and babies nationwide. Perchlorate poses a risk for pregnant women, newborns and young children by interfering with thyroid hormone, which is critical for optimal development of the brain and nervous system. Perchlorate is found in drinking water in at least 26 states, and 20-40 million people could be exposed to this chemical.

Several states have set drinking water standards or guidelines for this chemical, but these standards vary widely, so it is critical for the EPA to set a national standard that is based on the best available science and that will protect public health. The EPA's own staff scientists have determined that your decision not to regulate perchlorate places some infants and young children above safe levels of exposure. The EPA's current draft scientific analysis should undergo independent scientific peer review and should be used as the basis for the regulation.

Response: The Agency believes that further review by the National Research Council would unnecessarily delay regulatory decision making for perchlorate. Therefore, EPA is not, at present, planning to request additional NRC review of issues related to perchlorate. Instead, EPA is issued a notice in August of 2009 seeking comments on a broad range of alternative approaches to the interpretation of the scientific data relevant to a regulatory determination for perchlorate in drinking water.

EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120.

Comment: Again, I urge you to reverse your decision and to set a national drinking water standard for perchlorate.

Response: See response to comment code 6120.

Commenter Name: Apparent Mass Mailing #5 - Clean Water Fund/Clean Water Action
EPA Document ID: EPA-HQ-OW-2008-0692-0689
EPA Comment ID: 20019
EPA Comment Code: 6120

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water.

* perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought;

* a national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Additional Facts

* Perchlorate is a harmful chemical used in rocket fuel, flares, and explosives.

* Perchlorate, even in small amounts, can impair the thyroid gland, which controls growth, development and metabolism.

* Developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills.

* EPA agrees that perchlorate has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher.

Response: See response to comment code 6120.

Comment: October 15, 2008

Stephen L. Johnson, Administrator Environmental Protection Agency - Mail Code 2822T 1200 Pennsylvania Avenue, N .W. Washington, D.C. 20460

Re: Docket ID No. EPA-HQ-OW-2008-0692

Dear Mr. Johnson:

The Santa Clara County Board of Supervisors does not agree with the preliminary determination of the Environmental Protection Agency (EPA) to not regulate perchlorate in drinking water at a national level.

Response: See response to comment code 6120.

Commenter Name: Pete McHugh
Commenter Organization: Santa Clara County Board of Supervisors
EPA Document ID: EPA-HQ-OW-2008-0692-0681
EPA Comment ID: 20022
EPA Comment Code: 6120

Comment: In September 2007, the State of California adopted a regulation to establish a maximum contaminant level (MCL) of 6 micrograms per liter for perchlorate in drinking water. However, a national standard is critical to safeguard water supplies throughout the nation and provide a baseline for enforcement by the EPA.

Community health is one of our Board's highest priorities. The protection of our residents through an enforceable drinking water standard for perchlorate is of paramount concern. It is for these reasons, the Santa Clara County Board of Supervisors urges your reconsideration of the need for a national perchlorate standard, and requests the EPA to protect public health by setting a Federal drinking water standard at or below the 6 micrograms per liter established in California.

Sincerely,

Pete McHugh Chair, Board of Supervisors

Comment: I request that the U.S. Environmental Protection Agency set a regulation for perchlorate in drinking water.

I have been concerned for some time about contamination in our water supply and have researched and now use water purification for my personal home drinking, cooking and bathing water.Perchlorate is one of the contaminants I am concerned about and try to control in our water supply.

I believe that perchlorate contamination is a nationwide problem and poses a general health risk if not regulated and monitored.

A national primary water regulation should include strict levels of perchlorate contamination that would protect the public health.

Please reconsider any decisions that reduce the control of perchlorate in our water supply.

Comment: Mr. Burneson, Tell EPA to extend the time comment period to 90 days. Thank you.

Luis Olmedo VÃ©lez Executive Director ComitÃ© CÃvico del Valle, Inc. 699 E Street Brawley, CA 92227 October 24, 2008

Eric Burneson Office of Ground Water and Drinking Water Standards and Risk Management U.S. Environmental Protection Agency

Dear Sir:

We are concerned that the EPAâ€™s failure to regulate perchlorate, as well as its unprotective proposed health reference level, will adversely affect the health and development of hundreds of thousands, perhaps millions of American children. In addition, expecting mothers will run the risk of permanently damaging the development of their unborn children. Not only will unborn children be affected, but the elderly population as well. Elderly people with a history of medical conditions will have a difficult time fighting off the effects that perchlorate may have.

Imperial Valley undergoes several environmental risks: The air is unclean. Pesticides are used regularly where people may come in contact with it. EPAâ€™s inability to contain perchlorate will only add to the already unstable environment in the Imperial Valley.

Response: EPA announced on October 10, 2008, its preliminary regulatory determination that a national primary drinking water regulation for perchlorate would not present "a meaningful opportunity for health risk reduction for persons served by public water systems." In response to requests from several stakeholders, EPA reopened the public comment period for an additional 15 days. Regarding EPA's determination to regulate perchlorate in drinking water, See response to comment code 6120.

Comment: Hello, It has come to my attention that the EPA has made a preliminary decision NOT to regulate perchlorate, a rocket fuel, with respect to contamination of drinking water. Considering both the divergent and grave effects to humans upon exposure to this chemical as well as recent studies showing that the chemical is dangerous at lower levels than previous thought, it is outrageous that the EPA would make such a poor decision. Please reconsider in favor of regulating perchlorate for the sake of our health and especially the health of our babies and developing fetuses.

Response: See response to comment code 6120.

Comment: Water is our most precious resource. I think the EPA needs to rethink its decision and start better protecting our water supply by regulating the amount of percholate in our drinking water. We should all be comfortable drinking from the tap in our homes, not constantly worrying about what contaminate has now found its way into our wells and water supplies. No one trusts the water as can be seen by the rise in purchasing of bottled water. It's your job to keep our water safe. Perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought. A national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Comment: Perchlorate has leaked into our water supplies everywhere, though particularly in the western and southwestern United States. It has turned up in our lettuce!

Ingredients of rocket fuel do not belong in our water. And if our tap water isn't clean, we're paving the way for the privatization of water, which means only the rich people will have water and the rest of us will have to fight each other for it.

Keep the water clean and get perchlorate out of our water. This one's a no- brainer.

Comment: Dear Sir/Madam:

It has come to my attention that the EPA, under the leadership of President Bush, has refused to regulate the presence of perchlorate in American drinking water. I urge the Agency to reconsider this decision. Perchlorate is a chemical that has been linked to numerous deleterious health effects in humans (and other animals)-- including serious changes in the thyroid gland, and a potential impact on cognition and normal fetal development.

For these reasons, I urge the EPA to regulate perchlorate very strictly.

Cordially,

Adam Nation Pittsburgh, PA

Comment: I urge the U.S. Environmental Protection Agency to rise above the political machinations surrounding this issue and reverse its preliminary determination on setting a regulation for perchlorate in drinking water. It is important that the American public can rely on the EPA making decisions based solely on scientifically determined health risks rather than on potential risks to special interest groups.

Response: See response to comment code 6120.

Comment: As an Engineer with an advanced degree, and an attorney, I am hereby urging the EPA (U.S. Environmental Protection Agency) to reverse its preliminary decision not to regulate perchlorate in drinking water.

My reasons include the following:

It is well established that perchlorate contamination is a nationwide problem. Perchlorate contamination has been shown (citations omitted) to have health effects at lower levels than previously understood.

A nationwide standard for primary drinking water regulation would provide an important and meaningful opportunity to protect the public health.

Perchlorate is a harmful chemical used, for example, in rocket fuel, flares, and explosives.

In small amounts, perchlorate can impair the thyroid gland, which regulates growth, development and metabolism.

It is well known that developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills.

The EPA has evidence that perchlorate has been found in at least 395 sites in 37 states, including 153 public water systems serving over 20 million people. Many reliable estimates suggest an even wider contamination.

This is an important public health issue that needs to be addressed in a responsible manner.

Response: Please see the response to comment code 6120.

Comment: To the EPA Personnel:

Your very name indicates your obligation to protect the environment and the vegetation and animal life (including people) dependent on that environment.

Knowingly allowing a dangerous contaminant into the water supply is paramount to putting it there with your own hand; and thus the dangerous ramnifications are on your shoulders personally.

Anything that has a negative effect should be regulated to the nth degree.

Perchlorate falls into this catagory.

I urge you to keep perchlorate out of our drinking water.

Thank you.

Response: See response to comment code 6120.

Comment: I urge the U.S. Environmental Protection Agency to regulate perchlorate in drinking water. The preliminary determination to refrain from setting such a regulation is irresponsible.

Perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought. As someone with an impaired thyroid gland I do not like considering the possibility that my drinking water might at any time contain a chemical known to cause thyroid damage. I hate to think (not that I will ever know) that this might be the cause, or that drinking contaminated water would worsen my health.

To ignore this problem and avoid setting a standard for perchlorate in drinking water is inappropriate. We citizens count on our government agencies to protect our water and our health and this is one example of where that is necessary.

Please reverse the determination.

Sincerely, Elizabeth Saunders Dorchester, MA 02122

Comment: Please regulate Percholarate in our water. We know that certain levels of this chemical have been found to be harmful. Why would you want to intentionally ignore the levels of this harmful chemical in the water that we drink? Please reconsider your decision concerning the regulation of this harmful checmical.

Kristin Flora South Riding, VA

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water. In California, perchlorate contamination in the groundwater has literally poisoned wells, and now it's okay, somehow?

Studies are already showing health impacts at lower levels than previously imagined and threatens of water supply. We need a national primary drinking water regulation to protect public health.

Bisphenol-A and Perchlorate are in a class of endocrine disrupters that impair the thyroid gland, which controls growth, metabolism, and development, especially in fetuses, infants and children.

EPA agrees that perchlorate has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher.

Response: See response to comment code 6120.

Comment: I can't believe there would even be a question as to whether or not to regulate the amount of perchlorate in water. What could possibly be a plausible reason? For the sake of children alone, this should be a no-brainer. The fact that there is even a question is frankly disgusting to me. Our government at work looking out for our best interest, obviously. I hope no one at the EPA has a pregnant wife or children gulping down the contaminated water. Do what's right, no matter what the cost!! We are talking about people's health here!

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water perchlorate contamination is a nationwide problem.

I do not, nor do I know if anyone can prvoe beyond a thin shadow of a doubt that perchlorate is harmful to life. However, when it comes to public good and the health of the country the fact that perchlorate is likely to be harmful in ways we know and don't know at this time is more than enough evidence to regulate this contaminant.

The job of the EPA is to protect the environment. The job the EPA is not to protect the corporations and the obscene corporate profits and practices that have led this country into a disastorous position financially and politically. I strongly urge you to work for the public good and give up the policies of the last eight years of protecting military/industrial complex at the expense of the US citizenry. A effective military does not have to be maintained at the expense of poisoning our own people. Do the right thing and regulate this poison in the environment.

Comment: To whom it may concern:

Your decision not to regulate perchlorate is irresponsible and will have tragic consequences for pregnant women and young children.

The 153 public water systems that are affected by this contamination will impact the lives of over 20 million people.

Please reconsider your decision. None of us would want to leave this sort of contamination for our children. I am sure none of the EPA personnel involved would want their children or grandchildren drinking water contaminated with perchlorate and you should not pretend that it would be OK for "other people."

Thank you for reconsidering your decision,

Beth Robelia, Ph.D.

Comment: Dear EPA:

I've been working with communities over the past eight years to reduce pollutants in stormwater as required by Phase II of the Clean Water Act. Countless hours and dollars later, communities are making headway in cleaning up our surface waters. My region of the county gets its drinking water from the Detroit River, where I'm sure the industrial history of the area has deposited perchlorate into the Detroit River. Please join communities in protecting our water resources and regulate this dangerous chemical in our drinking water. You have required communities to minimize pollutants in our lakes and streams. Now please do your part in continuing our progress in protecting our drinking water.

Thank you.

Comment: Perchlorate does not belong in water, and it should be a right of every American to have drinking water free of chemical contamination. My family is suffering from autoimmune issues. We notice more and more people who are dealing with chronic health issues and strongly believe that our country's loose use of synthetic products could be to blame. Keeping perchlorate out of drinking water is a no brainer. Why don't we start here!

Response: See response to comment code 6120.

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water.

perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought; a national primary drinking water regulation would provide a meaningful opportunity to protect public health.

I live in Michigan and believe that perchlorate is in my drinking water. I have a thyroid problem that I suffer with for the last 2 1/2 years. I have no insurance and have to pay for specialist and perscriptions out of pocket.

Is your purpose in Washington to help save our viable drinking resources and the citizen's with which you represent?!

Comment: To whom it may concern,

It is crucial to my family as well as everyone I know that every measure be taken to protect our groundwater.

Living in Michigan, we have watched for decades upon decades as our environment has been decimated with toxic pollutiion. Everyone in this area lives near a "superfund" site.

This is a huge issue for citizens, probably more than any government agency realizes. Cancer has become a plague in southeast Michigan.

Please do everything possible, setting up whatever measures are needed to stop the contamination our water supply.

Sincerely, Laurie Dixon

Leonard L. Schumacher 16516 Denise Dr. Austin, Texas 78717

U .S. Environmental Protection Agency Attn: Steve Johnson, EPA Administrator Arei1 Rios Building 1200 Pennsylvania Ave. N .W. Washington, DC 20460 Dear Mr. Johnson,

I have read recently about the toxic rocket fuel ingredient (perchlorate) that has been found in public water supplies at 395 sites in 35 states, and that the EPA does not intend to rid it from the water.

The levels found are high enough to affect thyroid function and pose developmental health risks, particularly for babies and fetuses according to some scientists. Great!!!

Combine this toxin with all the other pesticides, insecticides, and the other many dangerous toxins and chemicals in our food supply, no wonder people are getting cancer.

Response: This is not a comment, a response is not necessary.

Comment: Dear Sir,

I am writing to you in response to the EPA's preliminary descision not to set a national maximum contaminant level for perchlorate (Docket ID # EPA-HQ- OW-2008-0068). I am a former resident of the San Gabriel Valley, California, and US citizen whose family was exposed to contaminated groundwater containing perchlorate for a significant length of time. I was exposed to perchlorate at elevated levels through drinking water and also now suffer Hashimoto's thyroid disease. Following discovery of the profound levels of contamination in the San Gabriel Valley, I have been very discouraged and disappointed in the apparent lack of concern for residents whose health has potentially been affected by long-term, historic, contamination. I appreciate the efforts that have since been made to clean up the toxins and to protect the drinking water of current residents, but that does nothing for residents that have already been exposed. In addition, I now reside in a state that does not have a MCL for perchlorate despite having known perchlorate releases. I am concerned for my children as well as the public's safety. It is for these reasons that I am very concerned about the EPA's preliminary decision not to set a maximum contaminant level for

perchlorate. I worry that we are facing another situation where we will be looking back wishing more appropriate safety measures had been implemented.

Response: See response to comment code 6120.

Comment: Perchlorate

Perchlorate is a very important issue for the drinking water community, and the perchlorate options detailed in the May 1st Federal Register notice raise many complex issues. Perchlorate provides EPA with a critical opportunity to appropriately implement the standard setting provisions of the 1996 SDWA amendments and the CCL/UCMR process. Additionally, there has been significant public interest generated by press coverage and subsequent interest by legislative bodies in certain states and at the federal level.

Building upon our position previously communicated to EPA in letters on February 2, 2005 and May 27, 2005, we recommend that EPA now make the decision to regulate perchlorate. AWWA believes that EPA has enough information to make a positive regulatory determination, and then to move forward with a proposed perchlorate regulation consistent with the requirements of the Safe Drinking Water Act.

We make this recommendation for the following reasons, absent any one of which we might make a different recommendation:

1. The National Research Council (NRC) and the Centers for Disease Control and Prevention (CDC) have found that perchlorate may have an adverse impact on the health of persons.

2. Perchlorate is known to occur in public water supplies in a number of states.

3. While occurrence data does not suggest that perchlorate occurs at levels of public health concern in the vast majority of public drinking water supplies and the population at risk appears to be small,

that group does include a sensitive subpopulation (pregnant women and developing fetuses) of significant concern.

4. The Greer data and the Reference Dose (RfD) recommended by the National Research Council (NRC) now make it possible for EPA to determine a protective level for perchlorate with a degree of confidence appropriate to a national primary drinking water regulation.

5. There are appropriate and reliable analytical methods for utilities and others to measure perchlorate concentrations in public water supplies, as documented by UCMR sampling, and laboratory capacity is not an issue.

6. A number of states are moving to regulate perchlorate and a patchwork of different regulations will confuse the public and the regulated community. And

7. Strong anecdotal data suggests that the lack of a perchlorate MCL has impeded a number of cleanups at hazardous waste sites. Cleanup at these sites could benefit public water suppliers, among others.

Response: See response to comment code 6120.

Commenter Name: Diane VanDe Hei
Commenter Organization: Association of Metropolitan Water Agencies (AMWA)
EPA Document ID: EPA-HQ-OW-2007-0068-0166
EPA Comment ID: 20275
EPA Comment Code: 6120

Comment: The notice also discusses perchlorate and does not provide a regulatory determination for this contaminant despite the availability of extensive data and high public concern. Because of the high public concern there is also high political interest. As local stewards of public health, we believe that if perchlorate presents a public health risk, then EPA should establish a maximum contaminant level for it. AMWA believes strongly in the regulatory process outlined in the 1996 Amendments. In the case of perchlorate, AMWA believes that the information available to the agency clearly points to a determination to regulate.

It appears that the agency has deferred the decision on perchlorate based solely on wanting a more accurate determination of the relative source contribution that might be attributable to drinking water. The notice states that, absent that information, a determination whether setting a national primary drinking water standard would provide a meaningful opportunity to reduce risk for people served by public water systems cannot be made.

Response: See response to comment code 6120.

Commenter Name: Diane VanDe Hei
Commenter Organization: Association of Metropolitan Water Agencies (AMWA)
EPA Document ID: EPA-HQ-OW-2007-0068-0166
EPA Comment ID: 20277
EPA Comment Code: 6120

Comment: At least nine states have addressed perchlorate through standards, health advisories, health based guideline levels, public advisories or other means. Utilities in states where no action has been taken face public perception and confidence problems at a minimum. EPA faces these same problems through continued inaction. A federal standard is needed in place of inconsistent state requirements.

AMWA urges EPA to keep in mind that a regulatory determination is the start of the regulatory process and not the end. Additional data is always gathered during the process. The final regulatory construct and requirements will be based on this data. All presently available data indicate that a positive determination is appropriate. Therefore AMWA believes that it is time for the regulatory process to begin. EPA can start this process outside the formal regulatory determinations and should do so. At minimum, a positive final determination should be made along with the determinations not to regulate 11 contaminants proposed in the present notice based on present data, and any additional information developed over the next several months while the agency's regulatory determinations are finalized.

If you have any questions about our comments, please do not hesitate to contact me or Erica Brown at 202-331-2820.

Comment: Perchlorate is only one of a cascade of foreign substances making its way into our drinking water. We are constantly learning of new, harmful substances whose interaction with our bodies and with other contaminates is unknown. The ONLY way we can preserve quality of our health as a nation is to ensure these foreign substances are not consumed by any of us. The EPA is supposed to PROTECT us from contamination, not facilitate it. This is our health, our future and our children we are talking about - not a group of hypothetical 'percentage of exposure' risks. Please wake up and start seeing our environment for the mess we have made it and help us clean it up, not add to the problem because someone talked you into it.

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water.

A national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Take the precautionary approach, or we will all pay later. It's harder to remove contaminants and try to make ammends with families impacted both emotionally and financially by the ramifications of toxics in their water. Now is the time to be a leader on this and other critical environmental issues.

Sincerely, Frances AnnLeary

Comment: As a concerned citizen with a family living by a major river and atop an already imperiled aquifer, I am distraught that EPA is even considering not regulating perchlorate levels in the water supply. How can my government be so unconcerned for its citizens' well-being? Perchlorate is a component in rocket fuel, and the science shows that even in low amounts it can be a threat to our health.

It is no favor to industry for the EPA not to set safety levels and monitor water for the presence of perchlorate. Should contamination at unsafe levels occur, the damage to the health of even a few citizens, much less to the large numbers who might be affected in any significantly populated area, would be a terrible blow to the industry as well.

It should be very clear that wise regulation is good for everyone. This is EPA's obligation, the very reason for your existence. This is not a quasi-market situation in which if one party fails, someone else will step in. EPA is our last best defense against man-made environmental hazards. We the citizenry are counting on you.

EPA Comment ID: 20359
EPA Comment Code: 6120

Comment: Re: Drinking water standards & Perchlorate: I find it ironic that the agency responsible for the safety and protection of both the American public and the national environment would consider that any amount of perchlorate - which is not a naturally occurring chemical - has an

acceptable level in the potable water of any mammal, whether human person or animal. To set any sort of standard/acceptable amount for percholorate presence is immoral, should never become legal and is, in the event, reprehensible. I understand that maintaining pure (perchlorate-free) water carries a cost: but it is nothing to the deep harm the chemical does to those who have no option but to drink it. Please, take the "high road" of consumer and environmental protection - in accordance with your mandate - and do not institutionalize the further poisoning of our water system. I would appreciate a written acknowledgment of my comment.

EPA Comment Code: 6120

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water.

On October 10, the EPA announced its preliminary decision not to regulate perchlorate in drinking water. I cannot understand why your agency would ever consider not regulating this contaminate. The purpose of your agency is to be the watchgard for the public in Protecting us from harmful substances. You need to side with the publics best interest in mind. If this causes manufacturers and industry to incur costs then they need to be responsible and include them in their cost of doing business just like all other repsonsible companies and manufactures.

Perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought; A national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Perchlorate is a harmful chemical used in rocket fuel, flares, and explosives. Perchlorate, even in small amounts, can impair the thyroid gland, which controls growth, development and metabolism. Developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills. EPA agrees that perchlorate has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher.

Reverse your preliminary determination and responsibly regulate this potentially harmfull substance.

Thank You

Greg Swanson

Comment: I would strongly urge the EPA to reconsider the perchlorate regulation for drinking water standards. I have experience with these chemicals first hand (I am a Captain on a regional Hazardous Material response team), and I have a great understanding of the short and long term effects of this type of chemical. Even minute amounts of this can cause harm to humans and animals alike. Please give due consideration to creating a standard for these chemicals.

Thank you.

Robert Prato Capt.

Comment: Safe Drinking Water is one of the main indicators of a developed country. Allowing percholate do go untested or regulated in our country's municipal waters is a mistake - one that every citizen will unknowingly make when they reach for a glass of tap water. With so much effort being made to turn people away from the fallacy of bottled water, why would we give people any more reason to doubt their local water sources?

Please consider testing water for percholate and making sure levels are well below the permissible amount!

Response: This regulatory action does not affect testing requirements for perchlorate in local jurisdictions. Please see the response to comment code 6120.

Comment: I do not want my drinking water standards loosened, especially when it comes to perchlorate. I understand that President Bush is trying to undo many important regulations that protect public health and our environment in his last few days in office. But EPA serves the American people, not just the President. EPA's job is to protect the public from harmful exposures whether acute or chronic. As well as to protect the environment for future generations. In the past eight years EPA has fallen down on this job. Regulations should be just as difficult to undo as they are to put in place to prevent politics and industry from having inappropriate influence on our nation's environmental health. Keep perchlorate out of our water. In addition, EPA needs to develop standards for atrizine as well. Pesticides should not be in our water either. And if the technology does not exist to remove these chemicals from drinking water then they should be banned from use or production.

Private Citizen Julia Burch 846 32nd Street Sarasota, Florida 34234

Response: Regarding regulation of perchlorate, See response to comment code 6120. Regarding regulation of atrazine, this is outside of the scope of this effort.

Comment: To Whom It May Concern:

The decision to put into place measures to regulate perchlorate in drinking water rest on the EPA's assessment of potential reduction of public health risk caused by the pollutant. It seems logical to me, and I hope to you, that if there exists ANY risk, or even the possibility of a risk to an population of American people, no matter how small, that regulation is necessary. If the EPA concludes that even a small sub-population is affected by perchlorate, then the EPA is saying, in their opinion, it is okay to have polluted drinking water as long as it only hurts a few. I believe this is bad policy and hope that you would agree. Second, Drinking water is an extremely valuable resource, and will become more valuable in the coming decades. Water tables all over the world are falling, climate change is causing drastic changes to our sources of drinking water, and skyrocketing world population is going to make drinking water more and more of a scare resource in the decades to come. It is imperative that we protect our drinking water against all possible contaminates.

Thank you for you time and attention to this issue.

Comment: To Whom it may concern, Please strengthen standards for our drinking water. Why would anyone in their right mind allow toxic substances to be in water that US citizens are relying on to be safe and pure. We are the only civilized country that even puts chlorine in our drinking water, which is suspected of causing health problems, and is being looked at as a major player in the increase of breast cancer. We are so behind other nations in taking a proactive stance against toxins in our food, water and consumer goods. When are we going to wake up? Canada has just banned bisphenol A,as have most civilized countries, yet our government is still telling us that it is safe- NOT! It is in liners of all canned goods, so how does one avoid it? We all can't grow and can our own food, we rely on the government to set safety standards and my government is sadly behind the curve. Please do not allow perchlorate in our drinking water. Sincerely, Marilyn Alvey

Comment: The health effects from ingesting low dosage perchlorate-contaminated water are not well known. But it's already known that it interferes with the body's iodine intake, causing an inhibition of human thyroid production. Regulation of this contaminent is clearly within the mission and mandate of your agency to protect humal health.

Further, since ammonium perchlorate which is used in solid rocket engine fuels has a limited shelf life and must periodically be replaced, a safe method of disposing of the chemical has to be designed and implemented. We cannot allow the buildup of perchlorate, notably in the Colorado Bassin, to continue unabated.

I urge you to reconsider your agency decision not to regulate this chemical.

Sincerely,

Francoise LaMonica 944 Centre Street Newton, MA 02459

Response: Please see the response to comment code 6120. Regarding commenter's statement "…since ammonium perchlorate which is used in solid rocket engine fuels has a limited shelf life and must periodically be replaced, a safe method of disposing of the chemical has to be designed and implemented", proper disposal of ammonium perchlorate falls outside of the scope of this regulatory action, as the Safe Drinking Water Act's authority is focused on whether or not the contaminant can be in public water systems.

Comment: November 3,2008 Stephen L. Johnson, Administrator United States Environmental Protection Agency 1200 Pennsylvania Avenue, N.W. Washington, D.C.. 20460 RE: Preliminary Regulatory Determination on Perchlorate; Docket ID No. EPA-HQ- OW-2008-0068

Dear Administrator Johnson:

The Children's Health Protection Advisory Committee (CHPAC) has been closely monitoring the Agency's approach towards perchlorate as a drinking water contaminant. Our March 2006 letter to you recommended that the Agency develop a federal Maximum Contaminant Level (MCL) for perchlorate. This recommendation was based upon the ability of perchlorate to disrupt thyroid hormone synthesis, lowering circulating levels of thyroid hormone, and the critical importance of thyroid hormone to brain development. Our concern over perchlorate has focused on in utero and

postnatal development, particularly for neonates whose exposures can be considerably greater than adults, and who lack stores of thyroid hormone. The life-long consequences of impaired brain development are sufficient to merit setting a protective MCL for perchlorate. Further, setting an MCL would mandate testing of public water supplies, and allow discovery of hot spots of contamination.

We are writing to you again on perchlorate because in the Preliminary Regulatory Determination on Perchlorate dated Oct 10, 2008, EPA decided against setting an MCL. This decision was based upon the establishment of a flawed benchmark, a Health Risk Limit (HRL) of 15 ug/L. This benchmark is clearly too high for infants as the Agency's own calculations show that an HRL of 15 ug/L would allow daily exposures to infants that are 2-5 times higher than the Reference Dose (RfD) (Federal Register, Vol 73, No.198, October 10, 2008, 60262-60282). The RfD is meant to be applied to everyone, yet in the case of perchlorate it is applied to adults but not infants. This decision does not recognize the science which supports the exquisite sensitivity of the developing brain to even small drops in thyroid hormone levels and the fact that neonates have much diminished stores of thyroid hormone relative to adults. The Agency must ensure that this life stage is adequately protected.

Response: See response to comment code 6120.

Commenter Organization: Children's Health Protection Advisory Committee
EPA Document ID: EPA-HQ-OW-2008-0692-0962
EPA Comment ID: 20424
EPA Comment Code: 6120

Comment: In summary, the CHPAC believes that all three conditions for setting an MCL are met and that the Agency must set an MCL for perchlorate. We request further communication with you and your staff regarding the Preliminary Regulatory Determination on Perchlorate. This is a critical and timely issue given the concerns over endocrine disruption by thyroid-active agents of various types and their potential to interact with other neurotoxicants to impair early life brain development. While many of these other neurotoxicants (heavy metals, pesticides, PCBs) have been aggressively targeted by USEPA, the lack of regulation of perchlorate is an obvious oversight that can readily be addressed. Thank you for your attention to this matter.

Sincerely, Melanie A. Marty, Ph.D., Chair Children's Health Protection Advisory Committee

Water Docket Environmental Protection Agency 1200 Pennsylvania Ave., NW Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2008-0692

Food & Water Watch, a Washington DC-based consumer advocacy organization, opposes the Environmental Protection Agency's Preliminary Regulatory Determination on Perchlorate.

Food & Water Watch hopes that the EPA will reconsider this preliminary determination and will issue a national primary drinking water regulation for perchlorate in accordance with the Safe Drinking Water Act.

Perchlorate has been found in the drinking water supply of 35 states and the District of Columbia. Widespread human exposure to perchlorate was confirmed by the Centers for Disease Control's NHANES study, which found that 100 percent of the 2,820 randomly selected study participants had detectable levels or perchlorate in their urine.[FNi: Blount, Benjamin C et al. "Perchlorate Exposure of the US Population, 2001-2002." Journal of Exposure Science and Environmental Epidemiology. 17: 400-407, 2007.]

The widespread exposure of the population to some level of perchlorate raises serious health concerns. Perchlorate can inhibit the thyroid gland's iodine uptake, potentially leading to hypothyroidism. Severe hypothyroidism during pregnancy can lead to abnormal fetal cognitive development, and even mild hypothyroidism during pregnancy is associated with subtle cognitive defects in children. Thus, perchlorate could alter fetal brain development, having lifelong cognitive effects for those affected.

The EPA's failure to regulate perchlorate in drinking water act places consumers - especially pregnant woman and children - at risk.

In response to this misguided determination, the EPA's own Children's Health Protection Advisory Committee has drafted a letter expressing its concern with the EPA's decision not to regulate perchlorate. Members of the committee claim that EPA rushed a decision on perchlorate without taking time to review all the latest peer-reviewed studies.

Given the vital importance of fetal central nervous development not only for long-term health and development of children, but also for the viability of fetuses, why would the EPA rush to a decision? Unfortunately the only conclusion we can draw is that the EPA has issued this determination to avoid strapping the Department of Defense with costs to clean-up near military bases, missile testing sites and chemical plants. While millions of consumers' health is jeopardized, it seems the budget concerns of the Pentagon or White House are driving EPA's decision.

This determination is clearly another instance of a regulatory agency shrinking from its responsibility to protect the American public. Instead of fulfilling your obligations under the SDWA, the EPA has once again folded to pressure.

Sincerely,

Wenonah Hauter Executive Director

Water Docket U.S. Environmental Protection Agency Mailcode 2822T 1200 Pennsylvania Avenue, NW Washington, D.C. 20460

Docket ID No. EPA-HQ-OW-2008-0692. Drinking Water: Preliminary Regulatory Determination on Perchlorate

The Massachusetts Department of Environmental Protection (MassDEP) is submitting the following comments in response to the United States Environmental Protection Agency's (EPA's) request for comment on its preliminary determination not to regulate perchlorate in drinking water at a national level, Docket ID No. EPA- HQ-OW-2008-0692 entitled "Drinking Water: Preliminary Regulatory Determination on Perchlorate". These comments were prepared by scientists in the MassDEP Office of Research and Standards (ORS) including Carol Rowan West, MPH, Director, ORS; Tsedash Zewdie Ph.D., Senior Toxicologist, ORS; and C. Mark Smith Ph.D., S.M., Deputy Director, ORS.

1. A Health Protective National Standard is Needed. MassDEP disagrees with EPA's draft decision not to regulate perchlorate at the national level and believes that a health protective national drinking water standard for perchlorate is both warranted and necessary to protect the health of our nation's children. Overall, EPA's assessment does not adequately support its determination to not regulate perchlorate for a sizeable number of United State' citizens, by disregarding elevated exposures and potential developmental effects in the neonate. This decision is inconsistent with basic precepts of public health protection.

EPA Comment ID: 20436
EPA Comment Code: 6120

Comment: In conclusion, EPA's determination that a national drinking water is not warranted is based on an incomplete assessment of the data and will place many of the nation's most vulnerable citizens, our newborn children and fetuses at an early stage of development, at risk. MassDEP believes that there is compelling evidence to support a national drinking water standard for perchlorate at a value well below EPA's HRL of 15 ppb.

For further information please contact Carol Rowan West at 617-292-5510 (Carol.RowanWest@state.ma.us) or C. Mark Smith at 617-292-5509 (C.Mark.Smith@state.ma.us).

Water Docket Environmental Protection Agency Mail Code: 2822T 1200 Pennsylvania Ave, NW Washington, DC 20460 RE: Docket ID No. EPA-HQ-OW-2008-0068

To Whom It May Concern:

Thank you for the opportunity to provide comments on the Preliminary Regulatory Determination on Perchlorate in Drinking Water proposed by USEPA, which was published in the Federal Register of October 10, 2008 (73 Fed. Reg. 60262-82 (October 10, 2008)). On October 7, 2005 the New Jersey Department of Environmental Protection (NJDEP) received from the New Jersey Drinking Water Quality Institute (NJDWQI), a legislatively created public advisory body, a recommendation to establish an MCL for perchlorate of 5 ug/L. The Department plans to propose such an MCL including monitoring and compliance determination requirements before the end of 2008 with adoption later in 2009. The NJDEP believes that having an MCL for perchlorate is good public health policy for both New Jersey and for the country as a whole.

There are two aspects of the proposal on which we would like to
Comment: 1) the proposal of a health reference level (hrl) for perchlorate of 15 ug/l. It is our understanding that an hrl is a drinking water concentration intended to protect individuals, including sensitive subgroups, from adverse effects resulting from a lifetime of exposure, similar to a lifetime health advisory or a maximum contaminant level goal. 2) The decision not to develop a regulatory standard (mcl) for perchlorate, and to develop guidance (a health advisory) instead, based on population exposed above the hrl.

Response: This is not a comment, a response is not necessary.

Commenter Name: Jeanne Herb
Commenter Organization: New Jersey Dept. of Environmental Protection
EPA Document ID: EPA-HQ-OW-2008-0692-1526
EPA Comment ID: 20452
EPA Comment Code: 6120

Comment: Based on the above comments, we strongly urge USEPA to reconsider its conclusion that 15 ug/L is a health protective concentration for perchlorate in drinking water. We also strongly urge USEPA to reconsider its determination to not regulate perchlorate. The New Jersey Drinking Water Quality Institute recommendations regarding perchlorate can be found at http://www.nj.gov/dep/watersupply/perchlorate_mcl_10_7_05.pdf. For further information or clarification about our position, contact Dr. Eileen Murphy at 609-984-6070, or Eileen.murphy@dep.state.nj.us .

Sincerely,

Jeanne Herb, Director, Office of Policy and Planning

C: Michele Putnam, NJDEP Eileen Murphy, NJDEP Barker Hamill, NJDEP Sandra Krietzman, NJDEP Betty Boros-Russo, NJDEP Gloria Post, NJDEP Perry Cohn, NJDHHS Mark Robson, Chair, New Jersey Drinking Water Quality Institute

Docket ID No. EPA-HQ-OW-2008-0692

Water Docket Environmental Protection Agency Mailcode: 2822T 1200 Pennsylvania Avenue, Northwest Washington, DC 20460

To Whom It May Concern:

Recently, the US Environmental Protection Agency (EPA) solicited comments for an action notice placed on the Federal Register relating to a preliminary regulatory determination for perchlorate in drinking water. The agency stated that levels of perchlorate found in drinking water systems were not at levels of concern and that there was no meaningful opportunity for health risk reduction through a national drinking water regulation. The Washington State Department of Health and the Oregon Department of Human Services disagree with EPA's conclusion and recommend that EPA reconsider the need for a national drinking water standard for perchlorate.

Extensive use and improper disposal of this highly water-soluble compound has led to groundwater contamination throughout the United States. To date, the extent of groundwater contamination has not been well characterized. It is known, however, that here in the northwest low levels of perchlorate have been found in groundwater in some tested areas of eastern Washington and Oregon.

Response: See response to comment code 6120. Regarding commenter's statement "…Extensive use and improper disposal of this highly water-soluble compound has led to groundwater

contamination throughout the United States", proper disposal of perchlorate is required by EPA's RCRA regulations and this subject matter falls outside of the scope of this regulatory action.

Comment: Opposition to EPA's Decision to Not Regulate Perchlorate - A Threat to the Great Lakes

James Barton, President - Underwater Ordnance Recovery jamesbarton@uwuxo.com Steve Pollack ESQ, - Director Blue Eco Legal Council steve@ecoesq.com

Removal of an estimated one million tons of unexploded ordnance and bulk containers abandoned on the floor of the Great Lakes is unlikely if the US EPA decision to deregulate perchlorates stands. Perchlorates are the most persistent munitions constituent leaching from decaying military explosives abandoned in a marine environment. Already beginning to show up at certain lakefront municipal water treatment facilities on both the US and Canadian sides, deregulation of perchlorates threatens the essential rational for removal of these "point source" emitters of perchlorates, and sets the stage for irreversible and unnecessary perchlorate contamination of the Great Lakes.

Rocket fuel is commonly provided as the most likely source for perchlorate contaminated drinking water. While perchlorates are used for that purpose, they are also a major component of conventional military explosives. Prior to WWII, Germany manufactured an entire class of civilian explosives based solely on perchlorates, and throughout WWII Russia manufactured numerous types of explosive filled projectiles containing up to 89% perchlorates by volume. The percent by volume of perchlorates used in period manufacture of US military explosives vary but 25% is a conservative number overall.

Unaware of the impending threat to the United States and Canadaâ€™s shared strategic asset known as the Great Lakes, the US Environmental Protection Agency is said to have bowed to pressure from the Pentagon, according to US Senate Environmental Committee Chair, Senator Barbara Boxer (D-CA), adding; "To see the Bush EPA just walk away is shocking". Paul Yaroschak, Pentagon Deputy Director for Emerging Contaminants denies this, saying; "We have not intervened in any way", adding "The EPA decision was based on the Safe Drinking Water Act".

The EPA has identified over 400 land based active or formerly used defense sites across 35 states where perchlorates have already been detected at dangerous levels in local aquifers, affecting an untold number of adjacent communities. Most of these sites have had little exposure to rocket fuel, but do have a documented history of military high explosive use or manufacture. Soils contaminated with decadeâ€™s worth of perchlorate laden high explosive residues have become "non- point" sources of pollution, and are as difficult and costly to remediate as the aquifers they continue to pollute every time it rains. By contrast, unexploded munitions and other defense wastes intentionally dumped and abandoned on the floor of the Great Lakes remain largely intact due to cold fresh waters, and fit the classic description of "point source" emitters of pollutants that can and must be eliminated.

The most common critical pathway for perchlorate to enter the human body is through contaminated drinking water. It primarily attacks the thyroid gland where it slows metabolic rate, which is why it was once used to fatten livestock and poultry before being linked to breast and testicular cancer. The thyroid glands of children are most susceptible to perchlorates, which can also be transferred to the fetus maternally. Women are said to be ten times more susceptible to perchlorate uptake than men.

The incredible persistence of perchlorate gives it the ability to migrate far from its point of origin, including into crops. Because of this persistence, the technical and economic challenges involved in attempting to eliminate perchlorate once it has entered an ecosystem illustrate that removal of point sources is the most economical course of action. Much of southern California for instance, is already forced to use perchlorate laced waters from the Colorado River, contaminated from a single DoD managed perchlorate manufacturing facility that used unlined retention ponds and operated in the middle of the Nevada desert; miles away from the Colorado River.

Some might be surprised to learn the scope of the problem in the Great Lakes, and canâ€™t imagine how or why it happened. The question is what we are going to do about it. Ask a Great Lakes resident and the answer is a foregone conclusion; pull the munitions and related defense wastes out of the Lakes before itâ€™s too late. While few are aware that high explosive filled munitions provide a substantial source of perchlorates, large numbers of munitions found elsewhere in a more advanced state of decay have been linked to a decline in fisheries. Where others were helpless to address such problems due to a lack of removal technology, we are not; but in fact are on the verge of choosing a similar fate.

The prime directive of the US Department of Defense is defending this nation against international strategic threats, and the projection of US influence and power; not long term domestic environmental threats, especially the ones they had a hand in creating. Allowing any waste originator into the decision making process regarding toxic waste clean up is a foolâ€™s game; and the DoDâ€™s dismal track record pertaining to underwater unexploded ordnance clean up bears this out. Where considerable resources are being devoted to protect the health and economic viability of individual communities from land based defense wastes that you can see; the health and economic viability of a nation is being neglected for what you canâ€™t.

Ask a US defense official what we are going to do about the defense wastes in the Great Lakes, and if you can get past the debate on whether the threat justifies remedial action, he will ask you who is going to pay for the clean up. At the upper levels in the Pentagon itâ€™s all about the money, and how long you can delay spending a dime on anything other than your prime directive. While that approach has worked well for them in the past, time is running out for the rest of us.

Deregulating perchlorate will not make it go away nor mitigate its harmful effects; using the Safe Drinking Water Act to justify it is an affront to our national identity; and its impact on the Great Lakes is a threat to our national security.

This action is clearly not the will of the men and women who proudly serve the US EPA, and does a disservice to the citizens whose interests they represent. Therefore, the decision to deregulate perchlorates must be delayed until after responsible leadership returns to the White House.

James Barton is an international expert on underwater ordnance, and regarded by some as the worlds leading expert on the subject.

Steve Pollack is the Director of Blue Eco Legal Council, specializing in environmental pollution at federal facilities.

Response: See response to comment code 6120. EPA acknowledges commenter's concern about the clean up of perchlorates in areas that serve as point source contamination to water, including The Great Lakes. The clean up of perchlorate contamination in the United States is related to EPA's CERCLA regulations and this subject matter falls outside of the scope of this regulatory action.

Comment: Docket Identification (ID) Number: EPA-HQ-OW-2008-0692 Preliminary Regulatory Determination on Perchlorate Re: Request for extension of comment period

I am writing to express my concern regarding the EPA's failure to regulate perchlorate, as well as the proposed reference level, which fails to protect - and will adversely affect -- the health and development of hundreds of thousands, perhaps millions of American children.

If the dangers we even only restricted to 17 million people alone that would be enough to take a more serious look at regulating, but the numbers of people affected is more like 20 to 40 MILLION + ! Already synthyroid is the number two prescribed medication in the country. This a drain on the insurance companies not to mention the devistation thyroid desease causes the patient. This chemical has been shown to cause thyroid problems. As a thyroid patient I can tell you every day is a struggle to keep control of my symptoms and I would not wish it on any one especially our children!

EPA Comment ID: 20466
EPA Comment Code: 6120

Comment: The regulation of perchlorate in our nation's water ways is rationally needed. From our drinking water to storm drains; streams into lakes; swamps to our forests; our land to our produce; into our wildlife and livestock, even our families, friends, and children, this regulation is needed. Our constitution demands this of us, and we must not be divided in makiong this stand; for our states, for our nation.

The People, their representives, the courts, the administration, they all have a ligitimate use of authority to provide for and protect ourselves. It would be an unjustice to the american people in allowing this pollutent to contaiminate our nation, in this way, and amount, any longer. Half-measures have to be stopped. We must take a firm stand, here and now, to show the american people, individuals and businesses, government and religion, neighbors and strangers, freinds and fowes, all over the world that the american government, its agencies, like the Environmental Protection Agency, are not going to stand idely by, and watch pollutants or contaiminates distroy our environment and severilly harm human beings and other inhabitants of this planet. We are reasonable,rationial, understanding, and forgiving, but we can not afford to be ignorant or blind, we can not afford to be walked over and abused any more, no matter in what situation, isuues, or relm.

Please take a stand, and strictly,within reasoning and speed, regulate perchlorate, (and other contaiminates and/or pollutants like) it is our duty to our posterity.

Thank you for your time, consideration, and civil service,

Respectfully,

Eric Keller Vice President, Phi Alpha Delta University of Detroit Mercy

EPA Comment Code: 6120

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water. Perchlorate contamination is a nationwide problem which has health impacts at lower levels than previously thought.

EPA agrees that perchlorate has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people -- and other estimates of human perchlorate exposure are higher.

Even in small amounts, perchlorate can impair the thyroid gland, which controls growth, development, and metabolism. Developing fetuses, infants, and children with thyroid impairment may suffer mental retardation, loss of hearing and/or speech, or deficits in motor skills.

Exposure via drinking water occurs constantly, every day, for extremely long periods of time. EPA should not shirk its responsibilities to ensure the safety of twenty million people via this route.

Please regulate the amount of perchlorate in drinking water. Twenty million Americans are counting on you.

Response: See response to comment code 6120.

Comment: My name is Leslie McCollom, and I am a private individual who practises law in Austin, Texas, at 808 West Avenue, Austin, Texas 78701. I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water. The reasons for my objections to your agency's preliminary determination is because perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought, according to research I have reviewed. I see no need to list all of the sources, since I am assuming that your agency has done its homework and reviewed all available data, research, and opinion on the effects of this chemical. A national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Perchlorate is a harmful chemical used in rocket fuel, flares, and explosives. Perchlorate, even in small amounts, can impair the thyroid gland, which controls growth, development and metabolism. Developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills as a result of consuming this chemical It is my understanding that the EPA agrees that perchlorate has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher. Under these circumstances, I believe the EPA has a legal duty to set a standard for this harmful chemical in drinking water, as well as in any and all bodies of water that are subject to regulation under the Clean Water Act.

Leslie McCollom O'Hanlon, McCollom & Demerath 808 West Avenue Austin, Texas 78701 (512) 494-9949

Comment: Maintaining current standards for perchlorate content is needed to clean up existing ground water contamination and prevent future spills. Although the cost is significant, the degradation of our environment is more costly; in increased health care costs, loss of productivity, and land value.

Response: This is not a comment. No response necessary.

Comment: Please reconsider the consequences of not regulating perchlorate. Is this water you will be drinking? Is this water your family will be drinking? If it were, would you be making this decision knowing the harmful effects perchlorate can have on the health of the people who are exposed to it. We have had enough with the past administration looking the other way in other situations. Let's not continue down the same road. You are the individuals that Americans hold responsible for our health and well being. If we can't count on you to do your jobs who can we count on? By choosing to support national regulations on public drinking water we know we can continue to trust you with health related issues. Please reverse your decision.

Sincerely, Susan Dunham

Comment: To the U.S. Environmental Protection Agency: I am a normal 30 year old professional woman from MN and was shocked and disgusted to learn about the EPA decided to not regulate perchlorate in drinking water. Please reverse your preliminary determination on setting a regulation for perchlorate in drinking water! It should be the goal of the EPA to protect the health and welfare of Americans, not to gamble with our future by allowing the contamination of our nation's water supply! In Minnesota we are now seeing the consequences of poor decisions like the one you are about to make. In many lakes and rivers it is no longer save to catch and eat fish, some waters are even unswimable. Consider the quality of limited resources you will be leaving for children and grandchildren. Do not take chances with something as critically important as keeping our nation's drinking water clean!! Thank you for your consideration, Molly P.,Minneapolis, MN

Perchlorate FACTS: Perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought;

a national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Perchlorate is a harmful chemical used in rocket fuel, flares, and explosives.

Perchlorate, even in small amounts, can impair the thyroid gland, which controls growth, development and metabolism.

Developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills.

EPA agrees that perchlorate has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher.

Response: See response to comment code 6120.

EPA Comment Code: 6120

Comment: It is a generally acknowledged fact that our planet is suffering from the dangerous effects of human industrialization, most publicly understood as global warming. More and more people are working to become responsible stewards of the earth by consuming less, buying organic and recycling; all the while an insidious danger flows quietly beneath our feet.

Perchlorate is an environmental danger widely known amongst scientific communities and government agencies, yet virtually unheard by the public. So much research has been done on the existence of perchlorate contamination in our water, food and milk supplies, and yet nothing is being done to regulate it. Much worse than a passive lack of action, is the very active suppression by certain U.S. agencies to protect their very specific interests, at the great expense to our country's environment and the health of those who inhabit it.

The EPA's website is full of information on how to contribute to the health of the environment from our classrooms to our beaches, from "purchasing green" to reducing water waste. It's wonderful to see the EPA helping people to make a positive impact on an individual level.

Isn't it time for the EPA to take a responsible stand and make the decision to regulate perchlorate in drinking water? Please, help protect the health of our people, ecosystems and future. Without water, we are nothing.

Thank you.

Comment: I am dismayed at the EPA's preliminary decision not to regulate perchlorate in drinking water. Perchlorate has been shown to inhibit proper function of the thyroid. As the father of a young son, and another child on the way, I am extremely concerned about dangerous chemicals present in our drinking water. Even a small reduction in thyroid function results in a loss of IQ, and increased behavioral problems. The EPA was on a sensible course to limit exposure to this dangerous chemical around 2002. I am appalled that the safety of our children is being ignored due to political considerations. I have been extremely upset at the course the EPA has taken over the last 8 years, allowing the White House and politics to sway decisions that should be made based on science and for the health and safety of the American people.

Comment: I am very concerned about the safety of US public water drinking water supplies. Keep the perchlorate out of the water. Test for it.

When contaminants are found, everyone in the region that uses that source for their household water needs to be informed and advised how to avoid consumption of the contaminants. We do not want to be forced to buy bottled drinking water - especially when we don't know what level of contaminants are permitted in the bottled water supply.

Thank you for your attention and please do all possible to insure that we have clean, safe drinking water.

Response: This regulatory action does not affect testing requirements for perchlorate in local jurisdictions. Please See response to comment code 6120.

EPA Comment Code: 6120

Comment: The determination of whether to control the level of perchlorate contaminates in drinking water supplies by the EPA has taken at least six years. Drinking water, groundwater or soil in hundreds of locations in at least 43 states is polluted with perchlorates. In 2004, eight states had advisories for perchlorate in drinking water, ranging from 1 to 18 parts per billion. Given the geographical magnitude of the problem and the diversity of current regulation, it is imperative that we have a Federal standard to protect everyone in the United States equally.

That standard should recognize the scientific study that has gone on to determine a safe level, and should not be politicized or modified to suit defense contractors.

Please set a standard of no more than 2 parts per billion.

Comment: As a resident of Tewksbury, MA and a journalist, I urge that the EPA require perchlorate testing of drinking water. I know the potential dangers of perchlorate to women and infants due to an corporate dumping of perchlorate into the Merrimack River in Massachusetts in

2004. That dumping went straight into Tewksbury's water supply, preventing residents from drinking the water for several weeks and costing the town a tremendous amount of money to locate the problem, stop the problem, and ensure the quality of the water. Testing public water supplies, particularly those drawn from rivers, ensures early detection of tainted water and early notification of at risk populations. Further, regular testing and early detection helps identify polluters early and stop the pollution. Not testing for perchlorate in the water supply is irresponsible from a public health and environmental perspective.

Response: This regulatory action does not affect testing requirements for perchlorate in local jurisdictions. Please see the response to comment code 6120.

Comment: November 5, 2008 Stephen L. Johnson, Administrator U.S. Environmental Protection Agency Ariel Rios Building 1200 Pennsylvania Avenue, N.W. Washington D.C . 20460 Re:Preliminary Regulatory Determination on Perchlorate Docket ID No . EPA-HQ-OW-2008-0068

Administrator Johnson:

We, the undersigned, represent the cities of Goodyear and Litchfield Park. Our communities are located in the West Salt River Valley area of metropolitan Phoenix in central Arizona and are impacted or threatened by the Phoenix- Goodyear Airport (PGA) North federal superfund site. The PGA North federal Superfund Site is an area of groundwater that has been impacted by TCE and perchlorate and it is this perchlorate contamination that prompts us to request that the EPA reconsider its determination and establish a national maximum contaminant level for perchlorate.

By way of background, surface water supplies in Arizona are limited and are fully allocated. Thus, groundwater is a vital water resource in the arid southwest providing a reliable future municipal supply for our growing communities. It is of such importance that Arizona classifies all aquifers as drinking water aquifers. Arizona, as with many other states, adopts the federal maximum contaminant levels (MCLs) as its own drinking water standards. Arizona also establishes aquifer water quality standards for the protection of its aquifers. Since Arizona's aquifers are classified as drinking water aquifers, the established aquifer water quality standards are generally equivalent to the MCLs.

Comment: The refusal of the EPA to regulate perchlorate in drinking water is an abrogation of the EPA's responsibilities.

Perchlorate is known to cause health problems to infants and adults that can be fatal or lead to permanent life-long disabilities.

Refusing to acknowledge this problem is tacit approval of those whose cause the pollution. The American tax payer is entitled to better protection than is currently provided, and should rightfully expect the EPA to manage this problem and hold the polluters accountable for cleaning up the problem and eliminating further contamination.

Richard Mead

Comment: Comments submitted to Environmental Protection Agency regarding: Preliminary Regulatory Determination on Perchlorate in Drinking Water RIN 2040-ZA02

I respectfully request EPAâ€™s consideration of the following comment regarding RIN 2040-ZA02:

I would urge EPA to reconsider setting a maximum contaminant level for perchlorate in drinking water for several reasons:

1. Perchlorate can interfere with the functioning of the thyroid gland causing serious health effects, especially in developing children.

2. If not regulated, the daily perchlorate intake can easily exceed the RFD of 0.7 Âµg/kg.

Comment: I think that anything that is as harmfull as rocket fuel is to humans should be regulated in our drinking water no matter how many PPM are deemed acceptable. By not doing so there is a big loop hole where millions of americans are then subjected to something that they are unaware of and may cause serious health hazards. First - on a personal note my mother had Non Hodgekings Lymphoma. Our family is unsure of what may have caused this. We had a well and if our water was tested who knows what that test would find. Or for that matter when people are going through a healh crisis it is better to be sure nothing like this would be introduced or reintroduced in their system. Second- Is it not better to try and regulate now and not in the future when there may be reason to have a huge multi person lawsuits. Does anyone really want to drink any persent of rocket fuel, maybe you folks at the EPA do but I don't! Thank you for your attention to this matter.

Comment: Too many environmental protections have been lost in the last 10 or so years and we certainly can not afford to be further concerned about the safety of our drinking water. To allow something as hazardous to health as perchlorate in our water should call for anyone involved in EPA or the Bush administration orchestrating these criminal acts to be prosecuted in court. It is indeed a criminal act to allow an agent of death to be harbored in the water we must all have to survive. Governments have pursued the removal of trans-fats and nicotine from the public scene and turn around and let this go on. Such a travesty!

Response: This is not a comment, a response is not necessary.

Comment: To: Stephen L. Johnson, Administrator, EPA From: Denise F. Sipple, Rumson, NJ Re: Enforceable limits for perchlorate in our drinking water

I recently lost my only child to cancer. Please protect the health of millions of American families and set enforceable limits for perchlorate in our drinking water. Specifically, I am writing to urge you reverse EPA's preliminary regulatory determination and set a protective drinking water standard for perchlorate as required by the Safe Drinking Water Act.

Perchlorate contamination in our food and water supplies is too widespread, and its toxic effects too well known, for continued inaction on this problem.

Response: See response to comment code 6120.

Comment: Really - there are enough health problems that need addressing in this country - autisim is just one example (I had never even heard of it as a child, currently though it's statistically on the increase). So, when there are health issues that can be addressed, and whose numbers can be keep lower, deregulation makes no sense. I'd like to hear anyone of you explain it to your children if your grandchild had mental retardation, or any other birth deficit, from the neglect you had in casting your vote against deregulation. Our clean waters must always be protected. Make your vote count - for the future generations! It may be your child and your grandchild that will be thanking you.

Comment: Dear EPA Staff,

As a drinking water professional, I generally abhor new regulations, but a national MCL on perchlorate is one thing that makes sense to me. After all, it occurs in drinking water at levels of public health concern far more often than than nearly any other chemical regulated under the SDWA, the two notable exceptions are arsenic and nitrate. If the same logic applied to perchlorate were applied to TCE, TCE would never have been regulated.

Response: See response to comment code 6120.

Comment: I live in Austin, Texas and have learned that Texas is one of the states where perchlorate is found in the water. I have a 20 year old daughter that has recently developed thyroid problems.

There is no genetic history of thyroid problems in our family. Perchlorate, even in small amounts can impair the thyroid gland.

I've also learned that developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills.

EPA agrees that perchlorate has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher.

I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water.

Please, protect our children!!!

Gladys Poorte

Comment: why can't we find a way for jet planes to remove excess fuel from their tanks without dumping the fuel on the ground? Sounds so simple, then we would not have dangerous levels of perchlorate in the ground water. I am apalled that this practice goes on. Your inept ability to see that this is a very real concern for people also amazes me. Pardon my forwardness, but my husband died from something related to this, and I am concerned that others may die needlessly because regulations are not either followed, or not created for the military which is the largest polluter in this country, and largest contributor to superfund sites throughout the country. My husband was an environmental engineer who worked on a superfund site, and I know first hand about groundwater contamination. His job was to clean up the sites! Please reconsider the measure that is being forwarded very seriously.

Response: See response to comment code 6120.

EPA Document ID: EPA-HQ-OW-2008-0692-1672
EPA Comment ID: 20591
EPA Comment Code: 6120

Comment: We urge you to protect Americans' health by regulating perchlorate in drinking water in accordance with the Safe Drinking Water Act. Please set the MCL for perchlorate in drinking water at no greater than 1 ppb.

Several states, including New Jersey, Massachusetts, and California have already addressed the issue of perchlorate in drinking water by either already setting or planning to set a MCL that is far lower than the current EPA recommendation. While none of these states have proposed a MCL as low as 1 ppb, their standards would still be far more protective of public health than the current EPA recommendation. But beyond these state borders, millions of people drink perchlorate contaminated water and depend on the federal government to protect them. EPA must fulfill this responsibility. Please regulate perchlorate in drinking water at no greater than 1 ppb.

Sincerely,

Jimmy Spearow, Ph.D. Sacramento Chapter, Physicians for Social Responsibility 911 Pennsylvania Place, #3 Davis, CA 95616 jlspearow@sbcglobal.net

Comment: Please re-consider your preliminary decision regarding perchlorate in drinking water. We need to protect our water resources; they are much more important than oil, gas, and coal! Without water of good quality, we will be faced with impossible problems, and it might be too late to correct them. Let's be pro- active, limit the amounts of perchlorate to an extremely tiny percentage, and not realize years from now there was a horrendous mistake made.

We definitely need to protect future generations from problems associated with perchlorate, which links have been proven to exist.

Please, do revise your position; water is essential, and it's been badly abused in the past. We definitely need to re-orient ourselves and protect our resources - our nation's well-being relies on it.

Comment: Gentlemen,

Higher perchlorate levels in drinking water? You have got to be kidding. Rocket fuel does not belong in drinking water, at any level!

Perchlorate is proven harmful to developing fetuses, infants and children and at lower levels than previously thought. Allowing perchlorate in drinking water is filfully negligent on your part.

Please fulfill your responsibility to the people and environment. Performing your duty under the law if a very important job; please do not shirk it now.

EPA Comment Code: 6120

Comment: Accordingly, docket ID No. EPA-HQ-OW-2008-0692 should not form the basis for national primary drinking water regulation.

Considering these issues, we conclude that EPA has based its argument for not regulating perchlorate contamination in public water systems on a literature that is both limited and ill focused. We believe that EPA has not performed a sufficiently "thorough review" of the literature, that it has omitted important information, and that it has failed to perform its due diligence in the interpretation and analysis of the information that it did present. To correct this, EPA must employ the CDC study (Blount et al, 2006a) as the point of departure for RfD determination, and must focus on the neonate and infant as the most sensitive population.

Response: EPA has determined to regulate perchlorate in drinking water (See response to comment code 6120). For further information about the RfD for perchlorate, please see the response to comment ID 28927 under comment code 2110. Regarding the comment for EPA to focus on the neonate and infant as the most "sensitive population," EPA published a Federal Register notice on August 19, 2009 seeking comments on additional approaches to analyzing data related to EPA's perchlorate regulatory determination. These comments were sought in an effort to ensure consideration of all the potential options for evaluating whether there is a meaningful opportunity for human health risk reduction of perchlorate through a national primary drinking water rule which included neonates and children.

Commenter Name: Mic Stewart
Commenter Organization: Metropolitan Water District of Southern California
EPA Document ID: EPA-HQ-OW-2008-0692-1784
EPA Comment ID: 20662
EPA Comment Code: 6120

Comment: In 2004, California's Office of Environmental Health Hazard and Assessment (OEHHA) adopted a public health goal (PHG) for perchlorate of 6 ppb. In October 2007, the California Department of Public Health (CDPH, formerly the Department of Health Services) adopted a primary drinking water standard (maximum contaminant level, MCL) of 6 ppb.

Although California has its own MCL for perchlorate, a national drinking water standard would assist in the clean-up of hundreds of U.S. Department of Defense facilities in Southern California and around the country. Since the detection of perchlorate contamination throughout the southwest Region and in hundreds of local groundwater wells, Metropolitan, its member agencies, and the drinking water community have called on the EPA to make a regulatory determination on perchlorate consistent with the tenets of the Safe Drinking Water Act.

Metropolitan wishes to offer the following comments:

* Regulatory Determination - With EPA's determination not to regulate perchlorate and therefore not set a drinking water MCL, Metropolitan is concerned that without Federal regulation potential clean-up efforts of contaminated surface and groundwater sites throughout the region and other parts of the Country may be impaired.

Response: See response to comment code 6120.

Commenter Name: Stephen A. Owens
Commenter Organization: Arizona Department of Environmental Quality
EPA Document ID: EPA-HQ-OW-2008-0692-1785
EPA Comment ID: 20666
EPA Comment Code: 6120

Comment: Numerous environmental, health and medical agencies, including the National Academy of Sciences, have documented and agreed that ingesting perchlorate through contaminated water, food and human breast milk may interfere with the production of thyroid hormones. This interference occurs because perchlorate "competes" with the uptake of iodide in the thyroid gland. Adding to this concern is EPA's own finding that the risk to infants is greater even when they have ingested low levels of perchlorate. Finally, the Centers for Disease Control found that ingesting perchlorate contaminated food and water may pose even a greater health threat for those women who have lower iodine intake levels to begin with.

Based upon the known occurrences of perchlorate in Arizona's water supply coupled with known human health concerns at detected levels, ADEQ disagrees with EPA's preliminary decision not to regulate perchlorate and strongly encourages EPA to reconsider the determination.

Thank you in advance for your consideration of these comments

Sincerely, Stephen A. Owens Director

Comment: I am deeply concerned by the EPA's decision to allow perchlorate in public drinking water. While allowing this substance to remain may be an initial cost- saving issue for some businesses, in the long term, perchlorate COSTS America a great deal of money, time, effort, and resources. The damage to infants and small children is incalculable; the costs to medically care for and to remedially educate the children damaged by deliberate pollution, such as perchlorate, are also incalculable.

Prevention is always CHEAPER than restoration and remediation! Please do not permit the pollution of our drinking water. Thank you for listening to my concerns.

Comment: Dear Mr. Johnson,

With respect to the decision in Massachusetts to lower the perchlorate standard in drinking water, it only makes sense to do the same nationwide.
http://www.boston.com/news/local/massachusetts/articles/2006/07/28/massachusetts_sets_state_standard_for_perchlorate/?p1=email_to_a_friend

Drinking water needs to be in its purest form to protect public health. Please keep in mind, that already two thirds of the country is using hydrofluosilicic acid, (fluoride), a hazardous waste byproduct of the phosphate industry, in drinking water. By allowing another toxic chemical in the drinking water, it only exacerbates the problem even further creating quite a toxic cocktail of chemicals that humans don't need in their water source. Please act on behalf of all, protect the population and keep the water clean.

Thank you! Karen A. Vilandry "Wasted Away"

Comment: Although perchlorate levels have perhaps dropped to neglible levels in water supplies as a whole, in 2004 the tap water in Tewksbury, Massachusetts could not be consumed because of elevated perchlorate levels. In fact, this condition was ultimately isolated to dumping by a manufacturing facility upstream on the Concord River, which merges with the Merrimack River, from which Tewksbury's water is drawn. It has since been addressed, but consider the implications for residents of Tewksbury, and specifically for children, had the condition not been detected, I don't believe this is a reasonable risk to assume. I certainly would not want my three small children to be harmed by such a decision.

Thank you.

Resident of Tewksbury

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water.

Perchlorate is used in rocket fuel, flares, and explosives. How can we possibly allow it to exist in our drinking water? The same water that our children drink. It is horrifying to think that the EPA does not consider regulation extremely important. Perchlorate, even in small amounts, can impair the thyroid gland, which controls growth, development and metabolism. Please protect us from this hazard. Sincerely, Ylana Stewart - Rockland, Massachusetts

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on not regulating for perchlorate in drinking water.

There is enough evidence showing a strong correlation between perchlorate and health problems. Please do the job your department was created for and protect the citizens of this country and the environment instead of large corporations and bowing to special interests that influence your department either directly or through congressmen who have been bribed through campaign funds. Pass regulations that will protect us today and tomorrow.

Comment: Clean drinking water is a limited natural resource - fought over in some regions - and is worthy of the full protection by the EPA. We must ensure that all business enterprises and municipalities are held to the highest siting and operating standards necessary to safeguard our water supplies. Of particular concern to me is the possibility of water contamination by perchlorate - an ingredient in rocket fuel. This must not be allowed to take place and the EPA must set strict contamination and testing guidelines.

Response: See response to comment code 6120.

Comment: October 28, 2008 Water Docket Environmental Protection Agency Mailcode: 2822T 1200 Pennsylvania Ave., NW. Washington, DC 20460.

Dear Sir or Madam,

I live in Los Angeles, CA and like many who live here, I am greatly concerned with the level of perchlorate in our water supply due to rocket fuel spillage. These worries have doubled recently as my wife and I are now planning to have our first child.

While I understand there is conflicting evidence when it comes to the study of perchlorate, it is widely accepted that percholorate can negatively affect the thyroid in a mother which is essential for proper development of the fetal brain.

No woman in the United States should be scared to drink tap water because she thinks it might cause damage to her unborn child. Rocket fuel has no place in our drinking supply IN ANY LEVEL - and certainly not at an increased level from what we used to believe was acceptable.

I trust you to do the right thing and require those who spill harmful chemicals in our water to pay for proper cleanup - and to keep "acceptable" levels of perchlorate as low as humanly possible.

Sincerely yours, Michael Peterson

Response: Regarding regulating perchlorate in drinking water, see response to comment code 6120. Regarding "requiring those who spill harmful chemicals in our water to pay for proper cleanup," see response to comment code 6300.

Comment: I grew up on Redstone Arsenal in Alabama(Aka Rocket City) and know first hand how damaging this chemical can be. My mother has had thyroid problems ever since my family moved there in 1984. Even though we only lived there for 5 years, and have zero history of thyroid problems in the family, she is now on medication for thyroid problems, and will be for the rest of her life.

To think that 20 years later, there is still zero regulation on Perchlorate is not only idiotic, but it is harming human health... The EPA has become a joke if you ask me under the Bush administration's last 8 years. It is their legal responsibility to protect American's from environmental harm, and yet here they are doing the exact opposite..

Why do i even pay taxes if this is what we get for our money? Should we honestly keep paying you to harm our loved one's health?

This government needs to move back to being FOR the people, and NOT for the Corporations....

Response: No response necessary, this is not a comment.

EPA Comment Code: 6120

Comment: I think there should be stronger regulations on Perchlorate and a law that requires a clean up should be enacted.

I lived next to a military base for 5 years and my wife went through three different pregnancies at that time. My research shows that Perchlorate can cause thyroid problems in pregnant women. During my wife's last pregnancy she developed a thyroid problem. My wife has to deal with a thyroid problem and we have to pay for thyroid medication for the rest of our lives possible because the EPA doesn't know how to do their job. There needs to be stronger legislation on this chemical. At least regulate it to the point of what was considered safe in 2002.

Thank You Dennis W.

Comment: It is very important the the Agency is fully aware of the risks of allowing substances to be disposed in our water. It is expected that, while there is ANY doubt that harmful consequences may occur, the Agency void any additional permission. The Agency is supposed to always protect the interests of the population and never take any action for which the consequences are not fully understood, when authorizing the increase/release of chemicals on the environment. Therefore, based on your study, I do not believe the Agency has all the necessary elements to put this rule in effect, and it is the agency responsibility to void it.

Response: See response to comment code 6120.

Comment: Water Docket, EPA, Mailcode 2822T 1200 Pennsylvania Ave Washington, D.C. 20460 * ATTN: Docket ID No. EPA-HQ-OW-2008-0692

To whom it may concern,

I believe that the EPA should institute strict regulations on perchlorate in drinking water. I believe that there is strong evidence to suggest that it's presence in our drinking water is a significant risk to public health. There have not been sufficient routine tests on the effects of this chemical and it should be strongly regulated until such time as it is absolutely confirmed that it poses no significant health risk. Thank you.

Richard D. Weaver

Comment: Mr. Townsend,

As a concerned citizen and mother of two children, I am appalled at the fact that the EPA would allow a chemical such as perchlorate to be in our drinking water. There are enough chemicals in our drinking water and air that we should spend more time and money cleaning it up rather than deciding if we should allow current levels to stay as they are. I don't care if I have to pay more taxes to have regulations tightened on the amount of pollution and contaminants a company is allowed to release into our environment. We only have one planet and we are not doing enough to take care of it and it's people. Please make sure that my children and there children can grow up in a safe environment free from all the unnecessary chemicals. Thank you.

Sincerely, Tina Donze

Comment: As a resident of northern New Mexico, in a region where high amounts of perchlorates have been found in certain water tables, especially those ajacent to Los Alamos National Laboratory, I strongly object to the EPA proposal not to regulate this poisonous substance. I realize the EPA has been seriously in decline during this current administration and systematically shedding responsibility left and right from protecting the American public from the depredations of out-of-control industries. But pretending a problem is not there will not make it go away. The EPA's shirking of responsibility makes it morally responsible for the health problems caused by its neglect. Please keep on regulating perchorates.

Comment: The proposed relaxation of this standard is hazardous to the health and safety of millions of Americans. Rather than relaxing the standard, it would be much more advisable to decrease the "safe" levels of Perchlorate and bring them back down to the 2002 standard. Barring that, leave them as they are. None of us want to be drinking higher levels of this component of rocket fuel, nor do we want to be drinking higher levels of any other chemical. Drinking water in America should be clean. Anything less is unacceptable and puts the health of millions of Americans at risk. ~ Tim Cranford, US Citizen and Taxpayer

EPA Document ID: EPA-HQ-OW-2008-0692-1914
EPA Comment ID: 20790
EPA Comment Code: 6120

Comment: It is my understanding that the EPA has decided, as a preliminary decision, not to regulate perchlorate in drinking water. That being the case, I am writing to request that you reverse that decision. I REQUEST THAT YOU REGULATE PERCHLORATE IN DRINKING WATER.

It is my understanding that perchlorate is harmful to people - e.g., that it can impair the thyroid gland. As a person who has taken Rx Synthroid daily for many years, I personally support regulation of perchlorate so that others won't have impaired thyroid function.

It is my understanding that developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech, or deficits in motor skills. As an educational advocate for families of children with disabilities, I support regulation of perchlorate in order to reduce the potential number of children with special needs in the future.

It is my understanding that perchlorate has been found in at least 395 sites in 37 states, including 153 public water systems serving over 20 million people. That's a public health hazard that cannot be ignored. So, for these and other good and sufficient reasons, I REQUEST THAT YOU REGULATE PERCHLORATE IN DRINKING WATER.

Thank you for your time and consideration.

Regards,

Lucy Margolis, President Educational Rights Advocates, Inc. 10430 SW 99 Street Miami, Florida 33176 Phone (305) 279-8855 Fax (305) 279-4880 Cell (305) 588-3858 Lucyedu@aol.com

Comment: I am greatly concerned about our exposure to toxic chemicals, both for environmental and personal health issues. Limiting our exposure can greatly increase our life-long health. Everything from household cleaners to beauty products and now to our drinking water seem to be loaded with toxins. The American people sometimes rely on government agencies to help protect it's constituents. It seems to me that if the EPA did not regulate a known toxin in our drinking water, then they would not be doing the service that they were organized for in the first place. I urge the EPA to regulate Perchlorate in our drinking water.

Thank you, Joshua Squire

Response: See response to comment code 6120.

Comment: I am appalled by the EPA's decision to NOT regulate perchlorate in drinking water. This is an astounding position for the agency to take since perchlorate can cause significant human health problems, even at levels much lower than previously thought. We and our children have enough insults to our health and immune systems each day without the EPA making it worse by working for corporations instead of the public at large. The EPA violates its fiduciary responsibility to the citizens of this nation by refusing to regulate a known toxin. Please reverse this decision. Please make the people in the EPA do their jobs. Protecting the public from these kinds of contaminants is what the agency exists to do. If the EPA does not step in and do what they were created for, then possibly it is time to do away with the EPA and replace it with an agency that will do its job.

EPA Comment ID: 20809
EPA Comment Code: 6120

Comment: Perchlorate contamination is a nationwide problem that can impact health at lower levels than previously thought. It is a dangerous chemical that affects the thyroid gland, potentially impairing the body's regulation of growth, development and metabolism. The EPA has found perchlorate in at least 153 public water systems. This chemical is used in rocket fuel and explosives. The companies creating these products with harmful side effects obviously aren't concerning themselves with the impact they are having on our environment. The government is allowing this. Ultimately, a regulation on the use of perchlorate would be the best answer to the health concerns of Americans. However, a national regulation of drinking water would also provide an opportunity to protect public health. Please, I urge the EPA to reverse its preliminary determination on setting a regulation for perchlorate in drinking water.

Thank you.

EPA Comment Code: 6120

Comment: Dear Official,

I am contacting you today to request the U.S. Environmental Protection Agency reconsider its preliminary determination to not set a regulation for perchlorate in drinking water. Perchlorate is a harmful chemical used in rocket fuel, flares, and explosives and even in small amounts can have very serious health impacts to our citizens. These include deficits in hearing, speech, motor skills and mental capacity.

Please look at the facts and consider regulating perchlorate in our drinking water.

Thank you,

Monica Juitt

Comment: Dear Sirs,

I always ask government agencies what their charge is. So, I wish to ask you what is your charge? Perchlorate is dangerous to human health and should thus be regualated. Government is to do for people what they cannot do for themselves. It is a great responsibility and yet a privilege to protect the people of this great nation. Not to regulate dangerous pollutants in our drinkng water seems like you have forgotten why this agency exists. Please answer your conscience when making decisions that impact our children.

Respectfull, Barbara Sullivan Citizen 2005 22nd Ave. NE Minneapolis, MN 55428

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water.

I do not want to drink perchlorate contamination in my water. This is a nationwide problem and has health impacts. I suggest that having a national primary drinking water regulation would provide a uniform standard that would protect public health at a federal level. This would save the cost of State by State regulations. This would also prevent long litigative process thru the individual states.

Thank You Dave Schaenzer

Comment: I would like to know how this is in some way justified by President Bush?? This is drinking water for the very same infants that Mr. Bush and company supposedly try to "save" from abortion. I guess once they are out of the womb, these babies are no longer politically important and can be given poison. Where are all the right wing evangelicals that are so angry about abortion but never say a word in protest of infants being provided poisoned water by our government?? What a conscience you must have Mr. Bush!! It is no wonder why you have been selected as one of the worst president's of our life time - I would say the worst in our entire history as a country. 27% approval rating?? do you have any shame? and to make matters worse, at the last minute of the presidency when people think you can't go any lower; you push forward with these insane laws! Amazing how selfish you can be. The days till your last day in office cannot come soon enough! Hope all your buddies with deep pockets are able to talk to your creator when its time for final judgement! Because from where I'm standing; you definitely have a long list of sins to account for!

Response: No response necessary, this is not a comment.

Comment: Pushing through this regulation is harmful to the general populous and should not be continued until an acceptable review period has been established. This kind of government regulatory process without adequate review and study is unacceptable and only panders to special interest.

Response: EPA announced on October 10, 2008, its preliminary regulatory determination that a national primary drinking water regulation for perchlorate would not present "a meaningful opportunity for health risk reduction for persons served by public water systems." In response to requests from several stakeholders, EPA reopened the public comment period for an additional 15 days.

Comment: I am outraged by this last minute rule changing. Will phone White House Monday to protest under cutting the public trust. The maximum safe level for perchlorate in drinking water is now 15 times higher than what was declared safe in 2002. Under this new standard, more than 16 million Americans are exposed to unsafe levels of perchlorate in their drinking water, and independent analysis shows anywhere from 20 to 40 million Americans at risk. Perchlorate has been found in the drinking water in 35 states in the U.S. This chemical has been linked to thyroid problems in vulnerable populations of newborns, young children and pregnant women. The relaxation of this standard is harmful to public health. outraged by this last minute rule changing.

Comment: It has been shown that perchlorate greatly impacts human health by interfering with iodide uptake into the thyroid gland. Its greatest impact is on newborns, young children, and pregnant women. While small amounts of perchlorate may not pose a serious threat, large amounts endanger human health and water resources. A lack of regulation for perchlorate leaves me concerned for the developmental health of those most vulnerable to the chemical's effects.

-Aaron Peterson

EPA Document ID: EPA-HQ-OW-2008-0692-2017
EPA Comment ID: 20850
EPA Comment Code: 6120

Comment: Clean Water Action has been concerned about perchlorate contamination for many years and has worked with communities facing perchlorate contamination of their water supplies and in several states where drinking water standards have been considered and/or set. Drinking water is a priority area for the organization and we work on many aspects of Safe Drinking Water Act implementation.

Clean Water Action urges the Agency to reconsider its preliminary determination NOT to set a Maximum Contaminant Level (MCL) for perchlorate at this time. With tens of millions of drinking

water consumers affected and given that perchlorate affects some of our most vulnerable people the most - infants and children - there is a meaningful opportunity for health risk reduction.

Response: See response to comment code 6120.

EPA Document ID: EPA-HQ-OW-2008-0692-2019
EPA Comment ID: 20856
EPA Comment Code: 6120

Comment: If EPA were serious about protecting the health of America's children, it would move forward with plans to develop a legal standard for perchlorate in drinking water. In the course of that effort, it should consider how other contaminants might contribute to the problem.

Finally, over the past decade, our understanding of the perchlorate threat has changed. Large sources of perchlorate pollution, associated with rocket-fuel production and other industrial activity, remain. However, it appears that perchlorate exposure is widespread at low levels also because of natural, agricultural, and incidental sources. To develop a public health strategy that addresses such exposures, we need a drinking water standard that requires the sampling of our water supplies at the low levels found to be a potential problem by the Centers for Disease Control. Even if it turns out that other factors-such as low iodine consumption-play a key role in the manifestation of thyroid dysfunction, such sampling is essential to protect the health of our children for decades to come.

Sincerely, (submitted electronically) Lenny Siegel Executive Director

Comment: As a member of the general public, I was horrified to hear that the EPA is considering NOT regulating perchlorate in drinking water. This chemical has been shown to be harmful to human and animal health.

As someone with a thyroid problem who has seen the number of people with thyroid problems increase over the last few decades, I was appalled to learn that the EPA has made a preliminary decision to not regulate a substance that has been shown to damage the thyroid gland.

In our time of bottled spring water for the wealthy, the failure to regulate perchlorate would disproportionately affect the health of the middle class and working poor. This is immoral and bad for health care costs.

The purpose of the government is to serve the needs of the people--not the needs of industry without any consideration for the people. I urge the I urge the EPA to reverse its preliminary decision and make a stand for moral stewardship of our nation's drinking water.

EPA Comment Code: 6120

Comment: Can anyone come up with one good reason to put Perchlorate in the drinking water? Aside from the obvious one, which is that it is the cheapest, and sneakiest, way for a corporation/government to get rid of a dangerous byproduct. As was done with fluoride, a byproduct of aluminum smelting, and ammonium, which killed all of my fish and thus, can't be all that good for you.

Adding Perchlorate to our drinking water is a ridiculous notion and everyone knows it. Wouldn't it be nice if people were truthful and responsible and took accountability for their actions?

Concerned Citizen, Justin White

Response: Perchlorate is not added to drinking water. There are three principal sources of the perchlorate in the environment: its use as an oxidizer (rocket propellants, fireworks, flares and explosives), its presence in Chilean nitrate fertilizer, and formation via atmospheric processes.

Comment: Please do not contaminate the water with one more chemical. We have a daughter affected with autism and is not able to detoxify herself very well due to low glutathione levels. This is common with children affected by autism. Whether or not the EPA finds that there is a safe amount that does not cause long-term affects on "people" doesn't speak to the large population of people that are having a hard time processing all the chemicals that are CURRENTLY out there.

Please hear our voices and don't add any more chemicals to the water that do (in some part) have a toxicity level (even though they haven't shown to have a large effect). Any toxicity is a lot of toxicity for a child on the spectrum!

Susie Bryan

Comment: Why bother having an EPA when it is unwilling to carry out its purpose-- to secure clean water (all water), air and land? Specifically, by denying its responsibility to regulate perchlorate in drinking water, the EPA is offending the leaders that chartered the institution and all people affected by its irresponsibility.

Perchlorate contamination is a problem nationwide. A small amount of this pernicious chemical poses a massive threat to our freshwater resources-- groundwater. There are communities, like some near me in California, that are nearly entirely dependent on groundwater. They can only expect to suffer grave health impacts from drinking perchlorate-laden groundwater. All the EPA has done here is to declare a Superfund site. That is unacceptable.

The EPA was created in order to be responsible for the government and government-sanctioned industrial pollution to our natural resources. Perchlorate found its way into our drinking water supply as a result of the Department of Defenses contracts with the aerospace industry. It sounds like paranoia, but I know the industry's and government's protective measures or accountability could not be further from the truth.

If you are not going to stand up to your responsibility, stop wasting my tax dollars and get out of a regulatory regime. If you are going to continue to pretend to be the department that secures clean water, air and land, then set perchlorate standards and clean-up superfund sites.

By all means, I expect a response-- both national and personal.

Sincerely, Caryn Mandelbaum, carynm5@gmail.com

Response: Regarding regulating perchlorate, see response to comment code 6120. Regarding cleaning up Superfund sites, see response to comment code 6300.

Water Docket US EPA Mailcode: 2822T 1200 Pennsylvania Avenue, N.W. Washington, DC 20460

Re: DOCKET ID No. EPA-HQ-OW-2008-0692 (Preliminary Regulatory Determination on Perchlorate--Reopening of Public Comment Period (November 28, 2008 Deadline)).

Dear Mr. Grumbles, and Mr. Burneson:

I just read through the Santa Susana Field Laboratory's Perchlorate Work Plan, the State Water Resources Control Board's Proposed Recycled Water Policy Staff Report, and after mulling through my recent letters addressing the State Water Resources Control Board's proposed review of California's Anti-Degradation Policy (Resolution 68-16), I am convinced more than ever that it is of the utmost importance the USBPA initiates development of a national regulation for perchlorate in drinking water ASAP because if the types of decisions on water quality issues made by California's State and Regional Water Quality Control Boards are indicative of trends in the other 49 States such state of affairs significantly impact Americans nationwide.

Sincerely, Mrs. Teresa Jordan

Enclosures:

EPA Comment ID: 20883
EPA Comment Code: 6120

Comment: Dear Administrator Johnson,

I am writing to urge you to reconsider EPA's preliminary determination not to regulate perchlorate in drinking water.

Perchlorate has been found in the drinking water supply of 35 states and the District of Columbia. Widespread human exposure to perchlorate was confirmed by the Center for Disease Control's NHANES study, which found that 100 percent of the 2,820 randomly selected study participants had detectable levels of perchlorate in their urine.

The widespread exposure of the population to some level of perchlorate raises serious health concerns. Perchlorate can inhibit the thyroid gland's iodine uptake, potentially leading to hypothyroidism. Severe hypothyroidism during pregnancy can lead to abnormal fetal cognitive development, and even mild hypothyroidism during pregnancy is associated with subtle cognitive defects in children. Thus, perchlorate could alter fetal brain development, having lifelong cognitive effects for those affected.

EPA's failure to regulate perchlorate in drinking water places consumers - especially children and pregnant women - at risk.

In response to this misguided determination, EPA's own Children's Health Protection Advisory Committee has drafted a letter expressing its concern with EPA's decision not to regulate perchlorate. Members of the committee claim that EPA rushed a decision on perchlorate without taking time to consider all the latest peer-reviewed studies.

Given the vital importance of fetal central nervous development not only for long-term health and development of children, but also for the viability of fetuses, why would EPA rush to a decision? Unfortunately, the only conclusion we can draw is that EPA has issued this determination to avoid strapping the Department of Defense with costs to clean up near military bases, missile testing sites and chemical plants. While millions of consumers' health is jeopardized, it seems the budget concerns of the Pentagon or White House are driving EPA's decision.

This determination is clearly another instance of a regulatory agency shirking its responsibility to protect the American public. Instead of fulfilling its obligations under the SDWA, EPA has once again folded to pressure.

Response: See response to comment code 6120.

Comment: To Whom It May Concern:

I am very concerned that the EPA is poised to walk away from monitoring perchlorate in our drinking water. Given the documented risk this contaminant poses to public health, this decision contradicts the purpose for which this agency was designed.

Southern California's main industries during the 1950's and 1960's were atomic energy and aerospace. Santa Susana Field Laboratory (SSFL) was home to over 30,000 rocket engine tests and the worst nuclear accident in US history. During the Cold War and Space Race, the Atomic Energy Commission (AEC) and Department of Energy (DOE) encouraged rampant environmental pollution in the name of production and experimentation, resulting in massive contamination to ground and surface water. Presently, SSFL languishes in a state of contamination. Perchlorate

remains a concern within our community; it has repeatedly tested beyond "safe" levels in drinking water, and thyroid issues are staggering in the neighborhoods surrounding SSFL. This is a nationwide concern, especially in communities that border military bases with a history of missile development.

The DOE continues to evade accountability for environmental crimes, which spanned decades. The EPA's cavalier approach to public safety regarding perchlorate sets a dangerous precedent.

Predictably, the public has been inadequately informed and provided with little time to offer educated comment before the opportunity to take part in the decision-making process expires. The EPA's attempt to rush this decision before administrative change - and while meeting only the minimum requirements for public participation (which are inept at best) - is very telling. The decision to cease monitoring for perchlorate in drinking water likely augurs trouble on the horizon for our citizens, the majority of which blindly trust agencies like the EPA to fulfill their responsibilities in an ethical, if not logical, fashion.

Sadly, the opportunity to access information and become involved in decisions like this one are difficult. Conversely, the public is bombarded with pharmaceutical ads which announce the availability of a wide variety of medication which is arguably necessary as a result of our routine exposure to a variety of toxins and pathways. Thyroid issues are steadily rising, and yet the government body tasked with this issue is willing to walk away from it. This does nothing but give rise to the possibility of collusion between EPA and pharmaceutical corporations. What is the pay-off for walking away from perchlorate? This is certainly not a decision motivated by commitment to public safety.

Office of Ground Water and Drinking Water (4601) Ariel Rios Building 1200 Pennsylvania Avenue, NW Washington, DC 20460-0003

To Whom It May Concern,

I support the EPA's decision to regulate the concentration in drinking water, but believe the perchlorate contamination level considered safe should be lowered. Perchlorate occurs both naturally and through manufacturing, and is found in rocket fuel, fireworks, and airbags. Perchlorate enters United States drinking water from improper disposal by test sites, military bases, and chemical plants. A 2005 report by the EPA stated that the chemical compound polluted soil, groundwater, and drinking water in 35 states and has contaminated 153 public water systems in 26 states. The report also estimated that 16.6 million Americans are exposed to perchlorate at levels scientists

consider unsafe. Perchlorate contamination in drinking water can have devastating effects, particularly on fetuses, newborns, and children.

Response: See umbrella response under 6120.

Commenter Organization: Environmental Working Group
EPA Document ID: EPA-HQ-OW-2008-0692-1432
EPA Comment ID: 20908
EPA Comment Code: 6120

Comment: The scientific evidence clearly points to the need for EPA to set a health protective drinking water standard for perchlorate - that is, a standard lower than the level shown to be associated with altered thyroid hormone levels in American women with low iodine intake. Unfortunately, EPA has relied on questionable science, an even more questionable computer model, and circular logic to justify its proposal to not regulate this harmful contaminant at all in our nation's drinking water. This is inexcusable.

EWG urges EPA to overhaul its poorly crafted assessment according to the points described in detail below and to live up to its mandate of protecting public health by setting a stringent drinking water standard for perchlorate.

Response: See response to comment code 6120.

Commenter Name: Anila Jacob
Commenter Organization: Environmental Working Group
EPA Document ID: EPA-HQ-OW-2008-0692-1432
EPA Comment ID: 20917
EPA Comment Code: 6120

Comment: Conclusion

As outlined above, EPA's preliminary regulatory determination on perchlorate is rife with errors, omissions, and wrong assumptions. EPA relies on a computer model that was generated using the now discredited Greer study. In addition, EPA chooses to ignore the valuable data from human studies like the Blount study that show potential health risks to millions of U.S. residents from perchlorate exposures much lower that the proposed HRL of 15 ppb. EPA also disregards the vulnerability of breast fed infants and young children, in whom current perchlorate exposures could potentially result in decreases in thyroid hormone levels that have long-term adverse effects on brain development and growth. Perhaps most egregious is EPA's finding that protecting 30,000 pregnancies annually is not a sufficient reason to regulate this dangerous contaminant in drinking water.

Response: See response to comment code 6120.

Administrator Stephen L. Johnson Water Docket, Environmental Protection Agency 2822T, 1200 Pennsylvania Ave., NW Washington, D.C. 20460

RE: Drinking Water: Preliminary Regulatory Determination on Perchlorate, Federal Register October 10, 2008, (73 FR 60262) (FRL-8727-6) Docket Number: EPA-HQ- OW-2008-0692

Dear Mr. Stephen Johnson,

The Pacific Institute would like to formally submit the following comments on the Environmental Protection Agency's (EPA) Drinking Water Preliminary Regulatory Determination on Perchlorate. After reviewing the Preliminary Determination and relevant literature, we do not agree with the EPA's determination that regulating perchlorate presents no "meaningful opportunity for health risk reduction for persons served by public water systems." While we recognize that the science upon which the determination is based has been contested, our comments address a number of further concerns, including the protection of vulnerable populations; the impacts that the determination will have on remediation efforts and future monitoring; and the criteria for what is considered to be a "meaningful opportunity" for protection of public health.

Response: This is not a comment, a response is not necessary.

Commenter Name: Lucy Allen
Commenter Organization: Pacific Institute
EPA Document ID: EPA-HQ-OW-2008-0692-1770
EPA Comment ID: 20928
EPA Comment Code: 6120

Comment: Ongoing monitoring of drinking water is needed to safeguard public health. The EPA's preliminary decision to not regulate perchlorate was contingent on the fact that a relatively small number of public water systems currently contain levels of perchlorate at unsafe levels. While this

may be true today, it may change, as perchlorate is widely used and easily leached. With uncertainties surrounding the extent of current contamination, and continued use of perchlorate,[FN11: Both Trumpolt et al. and Aziz et al. identify uncertainties in how current uses of perchlorate, e.g. in road flares and fireworks affect groundwater perchlorate levels. See footnotes 12,13.] the EPA should set a Primary Drinking Water Regulation to make ongoing monitoring mandatory.

According to GAO 2007, federal and state agencies have found perchlorate in groundwater, surface water, soil, or public drinking water systems at almost 400 sites in 37 states, in concentrations ranging from 4 ppb to more than 3.7 million ppb. The GAO contends that "it is difficult to determine the extent of perchlorate in the United States or the status of any cleanup actions because EPA does not centrally track or monitor perchlorate detections, environmental releases, or cleanup activities."

Many potential sources of perchlorate contamination in the U.S. exist, including munitions manufacture and disposal, use of explosives in rock blasting, manufacture and use of fireworks, manufacture and use of safety flares, and use of Chilean nitrate fertilizers.[FN12: Trumpolt, C., M. Crain, G. Cullison, S. Flanagan, L. Siegel, and S. Lathrop. (2005). Perchlorate: Sources, Uses, and Occurrences in the Environment. Retrieved Oct 27, 2008 from http://yosemite.epa.gov/r10/CLEANUP.NSF/PH/Arkema+Technical+Documents/$FILE/Perchlorate-Sources-Occurance-In-The-Environment.pdf.],[FN13: Aziz, C., R. Borch, P. Nicholson, and E. Cox. (2006). Alternative Causes of Wide-Spread, Low Concentration Perchlorate Impacts to Groundwater. GeoSyntec Consultants, Guelph, ON, Canada. Retrieved Oct 27, 2008 from http://www.springerlink.com/content/p8m017624280752w/.] In addition to these ongoing uses of perchlorate, there may be environmental contamination from historic releases, for example from manufacture and disposal. This widespread use is likely to lead to further water contamination, as perchlorate is readily leached from soil into groundwater due to its high solubility and persistence in the environment.

Response: See response to comment code 6120.

Commenter Name: Lucy Allen
Commenter Organization: Pacific Institute
EPA Document ID: EPA-HQ-OW-2008-0692-1770
EPA Comment ID: 20929
EPA Comment Code: 6120

Comment: The EPA determined that regulating perchlorate in drinking water does not pose a meaningful opportunity to protect public health-even as its report recognizes that 900,000 people will remain exposed to perchlorate at levels that could exceed the health reference level, up to 30,000 of which are pregnant women at any given time. Protecting the health of these individuals, even if it is a small group, is significant, and the federal government has the capacity and responsibility to do so.

Response: See response to comment code 6120.

Commenter Name: Ron Curry
Commenter Organization: New Mexico Environment Department
EPA Document ID: EPA-HQ-OW-2008-0692-1796

EPA Comment ID: 20931
EPA Comment Code: 6120

Comment: In its preliminary determination, EPA has tentatively decided not to promulgate maximum contaminant levels (MCL's) for perchlorate under the federal Safe Drinking Water Act (SDWA), 42 U.S.C. [sections] 300f to 300j-26. The Environment Department strongly urges EPA to reconsider this preliminary determination and to promulgate an MCL for perchlorate at a level that will protect human health, including the health of subgroups at greater risk of adverse health effects.

Response: See response to comment code 6120.

Comment: Comments from Environmental Defense Fund on the Preliminary Regulatory Determination on Perchlorate Docket EPA-HQ-OW-2008-0692 Federal Register / Vol. 73, No. 198 / Friday, October 10, 2008

Prepared by Caroline Baier-Anderson, Ph.D. Senior Health Scientist

Submitted to Docket: November 28, 2008

On behalf of Environmental Defense Fund, a non-profit, non-partisan, non- governmental environmental organization that combines law, policy, science and economics to find solutions to today's most pressing environmental problems, we offer the following comments on the Preliminary Regulatory Determination on Perchlorate.

Environmental Defense Fund would like to express our strong disagreement with the Environmental Protection Agency's (EPA) Preliminary Regulatory Determination on Perchlorate, as presented in the Federal Register / Vol. 73, No. 198 / Friday, October 10, 2008. EPA has determined that a national primary drinking water regulation for perchlorate would not present a meaningful opportunity for health risk reduction. We believe that this decision is predicated on a flawed reference dose, and the incorrect application of a physiologically based pharmacokinetic model, leading to the derivation of a faulty health reference level. Below we lay out the details of our criticism, and offer alternative views that justify promulgation of a stronger standard for perchlorate.

Response: Regarding promulgating a perchlorate standard, see response to comment code 6120. Regarding the perchlorate reference dose, see response to comment 28863 under comment code 2110; regarding application of the PBPK model, see responses to comment codes 2400 and 2410; and regarding derivation of the health reference level, EPA derived potential alternative HRLs for 14 life stages (age groups) using the RfD and life stage-specific exposure information in the August 9, 2009, notice (74 FR 41883; USEPA 2009b). These levels range from 1 µg/L to 47 µg/L and are the concentrations of perchlorate in drinking water that may result in total perchlorate exposures (from food and water) greater than the RfD for individuals at each life stage. These HRLs are calculated based on individuals who consume an average amount of perchlorate from food (except for

pregnant women where EPA used a 90th percentile dietary intake estimate), but who consume equal or more water on a per body weight basis than 90 percent of their cohorts.

Commenter Name: Caroline Baier-Anderson, PhD

EPA Document ID: EPA-HQ-OW-2008-0692-1797
EPA Comment ID: 20954
EPA Comment Code: 6120

Comment: EPA Can Reduce Health Risk by Promulgating a Perchlorate Standard

In summary EPA has an opportunity to significantly reduce risks to human health by promulgating a perchlorate standard, providing that the reference dose is based on CDC data, taking into consideration sensitive subpopulations, including women of child-bearing age that are not receiving sufficient iodine, and the fact that hypothyroidism in the US is not only prevalent, but under-diagnosed and under-treated. All else follows from this initial calculation, as a reference dose based on the appropriate consideration of these factors will result in a more realistic estimate of the number of US citizens potentially impacted by perchlorate in drinking water. Such an analysis, based on more realistic assumptions, and newer, more accurate data, will provide concrete support for EPA action.

U.S. Environmental Protection Agency Office of Water Docket (Mailcode: 2822T) 1200 Pennsylvania Avenue, NW Washington, DC 20460

Comments from the NATURAL RESOURCES DEFENSE COUNCIL on the Drinking Water: Preliminary Regulatory Determination on Perchlorate

Docket EPA-HQ-OW-2008-0692 Federal Register / Vol. 73, No. 198 / Friday, October 10, 2008

SUMMARY

On October 10, 2008, EPA announced a preliminary regulatory determination not to set a health-protective standard perchlorate in drinking water.[FN1: 73 Fed. Reg. 0262 (Oct. 10, 2008).] The Federal Register notice states that: "The Agency has determined that a national primary drinking water regulation (NPDWR) for perchlorate would not present 'a meaningful opportunity for health risk reduction for persons served by public water systems.'" EPA sought comments on whether setting a national primary drinking water standard for perchlorate would provide a meaningful opportunity for health risk reduction for persons served by public water systems, on the scientific data and supporting analyses for this determination, and on its use of a revised physiologically-based pharmacokinetics (PBPK) model. With this FR Notice, EPA has proposed a health reference level (HRL) of 15 ppb as the maximum contamination level of perchlorate that could be in drinking water, and still keep daily human consumption levels from exceeding the reference dose (RfD) of 0.7 ug/kg/day.

After careful review of these documents, NRDC concludes that EPA's determination is legally flawed. EPA must regulate a contaminant if it may have an adverse effect on human health, if it is known to occur (or there is a substantial likelihood that the contaminant will occur) in public water systems with a frequency and at levels of public health concern; and if its regulation would present a meaningful opportunity for health risk reduction for persons served by public water systems.[FN2: 42 U.S.C. [section] 300g-1(b)(1)(A).] For perchlorate, each of these three requirements are met, and therefore, underscore that EPA must regulate its presence in drinking water. First, EPA's preliminary regulatory determination acknowledges that perchlorate may adversely affect human health.[FN3: 73 Fed. Reg. 60275 (Oct. 10, 2008).] Second, as explained in more detail below, despite EPA's contention, perchlorate is known to contaminate the drinking water systems serving millions of people at levels where adverse human health effects occur. And third, setting an appropriately stringent MCL will lead to lower levels of perchlorate ingested by hundreds of thousands of infants, thereby offering a concrete and meaningful reduction in human health risks.

Procedurally and scientifically, EPA has made this preliminary determination in an arbitrary and capricious manner. Procedurally, the FR Notice announcing EPA's preliminary determination was issued for public comment even before EPA had received the peer review report on the PBPK model, which EPA used to justify the HRL. Moreover, it is our understanding that EPA is still awaiting peer review comments on the proposed HRL itself. The preliminary determination also fails to address the recommendations of the Science Advisory Board Drinking Water Committee (SAB DWC). Scientifically, the basis for EPA's determination fails to appropriately incorporate data demonstrating population level effects at environmentally relevant levels of exposure. In effect, this data severely undercuts EPA's conclusion that there would not be a sufficient benefit for protecting public health by setting a drinking water standard for perchlorate. The agency's apparent decision to ignore relevant scientific information, in reaching a decision not to regulate this dangerous and widespread drinking water contaminant is not a proper exercise of EPA's decision-making process. Instead of rushing forward without the benefit of full consideration of the most recent scientific evidence (and scientific advice), EPA should carefully review and analyze the results of the peer review of the PBPK model and the HRL, allow the public an opportunity to review and analyze those results, and request an SAB DWC review prior to making a determination on how to address perchlorate contamination. EPA's failure to fully consider the existing data on the effects of perchlorate on vulnerable sub-populations, and short-circuit the process of peer review and public comment on the models upon which their determination is based, is arbitrary and capricious. Furthermore, EPA's conclusion regarding the potential health benefits of setting a drinking water standard for perchlorate is in error, and its preliminary decision not to set a regulatory standard for perchlorate, if finalized, would violate the Safe Drinking Water Act.

Response:
EPA has reversed its October 2008 preliminary determination not to develop an NPDWR for perchlorate and now concludes, based on the analysis presented in the final regulatory determination, that there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern. The Agency has determined that regulation of perchlorate presents a meaningful opportunity to reduce health risk for persons served by public water systems.

Please see the response to comment code 6120. EPA disagrees with the commenter's statement that procedurally and scientifically, the preliminary regulatory determination for perchlorate was made in

an arbitrary and capricious manner. EPA considers the best available science when developing drinking water standards, as required by the 1996 amendments to the Safe Drinking Water Act. In applying these principles, "best available" usually refers to the availability at the time an assessment is made. In the August 2009 notice, EPA stated that it was re-evaluating how best to incorporate the PBPK modeling analysis into its evaluation of perchlorate — if at all. The Agency sought comments on ways to use the PBPK modeling analysis to inform the regulatory determination. Regarding the commenter's concern about the peer review of the PBPK model, please see the response to comment code 6400. Additionally, EPA discussed the key scientific issues raised by external peer reviewer commenters on the Interim Drinking Water Health Advisory for perchlorate in the August 2009 notice and in today's notice. A summary of peer review comments and EPA responses on the Interim Drinking Water Health Advisory are available in the docket for today's notice (Docket ID No. EPA–HQ–OW–2009–0297) at http://www.regulations.gov. EPA has further considered peer reviewer and public comments regarding the use of the PBPK model to inform today's regulatory determination for perchlorate, please see response to comment ID 20432 in comment code 5220 for a more detailed discussion.

EPA disagrees that the PBPK model should have been reviewed by the SAB because the model and draft report underwent a formal external peer review by eight experts in accordance with EPA guidance (see response to comment code 6400). Additionally, per SDWA, EPA will consult with the SAB prior to proposal of the perchlorate maximum contaminant level goal and NPDWR.

Please see the response to comment code 5220 for a further discussion of EPA's determination that regulation of perchlorate in drinking water systems presents a meaningful opportunity for health risk reduction for persons served by public water systems.

EPA Comment ID: 20982
EPA Comment Code: 6120

Comment: Based upon the evidence in the record, as discussed in greater detail below, NRDC urges EPA to reverse course, and set a national primary drinking water standard for perchlorate that is protective of sensitive sub-populations. EPA should not set a HRL at 15 ppb; rather, given the most current data available, NRDC believes that that a truly health protective standard would fall below 1 ppb.

Response: See response to comment code 6120.

Commenter Name: Jennifer Sass, PhD.
Commenter Organization: Natural Resources Defense Council
EPA Document ID: EPA-HQ-OW-2008-0692-1988
EPA Comment ID: 20988
EPA Comment Code: 6120

Comment: NRDC strongly objects to EPA's preliminary determination on perchlorate because the conclusions are not based on a comprehensive review of the best available science (as explained in more detail below) and are not supported by the PBPK model findings, or by EPA's expert scientific

advisors on the Children's Health Protection Advisory Committee.[FN22: Letter from Melanie Marty to Administrator Johnson regarding Preliminary Regulatory Determination on Perchlorate (November 3, 2008, PDF) http://yosemite.epa.gov/ochp/ochpweb.nsf/content/perchlorateletter.htm/$file/PerchlorateLetter.pdf] In fact, drinking water that is contaminated with perchlorate at the HRL would leave infants and young children exposed to excessive and unsafe levels of this toxic chemical.

Response: Please see the response to comment ID 20979 under comment code 6120.

Water Docket Environmental Protection Agency Mail Code: 2822T 1200 Pennsylvania Ave., NW Washington, DC 20460 RE: Docket ID No. EPA-HQ-OW-2008-0692

To Whom It May Concern:

The Association to Preserve Cape Cod (APCC) is a non-profit environmental organization dedicated to the preservation of Cape Cod's natural resources and quality of life. Founded in 1965 and currently representing over 5,500 members, APCC is the oldest and largest environmental organization on Cape Cod.

On behalf of APCC, I am pleased to submit comments on the Preliminary Regulatory Determination on Perchlorate in Drinking Water proposed by USEPA. APCC urges USEPA to reconsider its determination to not regulate perchlorate. There are a significant number of water resources across-the country that contain perchlorate; 35 states have detected dangerous levels of perchlorate in drinking water. The full extent of the pervasiveness of perchlorate is still unknown. In addition to drinking water, it is also found in produce and dairy products, likely coming from water used to irrigate crops and water livestock. Perchlorate is also extremely persistent, meaning it has the potential to migrate far from the source of contamination, polluting entire watersheds.

The health consequences of ingesting perchlorate are significant, largely impact infants, and can be transferred maternally to a fetus. Perchlorate causes a reduction of the thyroid hormone production. The thyroid hormone is critical for muscle and brain development. Where protecting the health and development of children is of paramount importance, such risks from perchlorate are unacceptable. Establishing a regulatory limit on perchlorate in drinking water is an important step in reducing this risk nationwide.

Sincerely,

Maggie Geist

Re: DOCKET ID No. EPA-HQ-OW-208-0692 (Preliminary Regulatory Determination on Perchlorate -- Reopening of Public Comment Period (Novemeber 28, 2008 Deadline)).

Dear Mr. Grumbles, and Mr. Burneson:

I am writing to ask that the Agency initiate development of a national regulation for perchlorate in drinking water.

Mr. Grumbles and Mr. Burneson, as a concerned citizen who has followed the significant impacts to people's and animals' health from water, soil, and air contamination due to DOW, NASA, and Rockwell International/Boeing Company rocket engines and nuclear reactors testing, lasers and other activities on the Santa Susana Field Laboratory (the SSFL, located in Simi Hills, in Ventura

County, California) for 19+ years, I was shocked when I read that the Agency would not be regulating perchlorate in drinking water systems around the Nation beacuse the determination significant ramifications for the County of Ventura, and, most especially, the City of Simi Valley!!!

Mr. Grumbles and Mr. Burneson, if I ever thought there was hope to finally have the SSFL included in the USEPA's Superfund List because of the Agency's cumulative findings, such grave news -- this determination coming years after perchlorate was included on the first (March 2, 1998) and second (February 24, 2005) Contaminant Candidate Lists (CCLs) -- just snuffed out the small light at the end of this very long tunnel! What travesty for the public trust, and the environmental justice program!!!

Mr. Grumbles and Mr. Burneson, this determination will allow the Ventura Countrywide MS4 NPDES Permit, and the municipal NPDES permits for the Cities of Thousand Oaks and Simi Valley, and the Camarillo Sanitary District waste water treatment plants to breeze through the Los Angeles Regional Water Control Board (LARWQCB) public review and comment period, and public hearing next time around -- no wonder the two subjects dropped off the radar.

EPA Comment ID: 21117
EPA Comment Code: 6120

Comment: EPA's opportunity to address perchlorate is substantial from a public health perspective given the risks this chemical can pose to early life development and its potential for occurrence in public water supplies. Sensitive test methods exist as do practical treatment options. Therefore, we urge EPA to reconsider its decision to not regulate perchlorate. In that reevaluation, EPA should utilize methodologies that ensure protection of all potentially sensitive receptors from the anti-thyroid effects of this chemical.

Please let us know if you would like additional information regarding the Connecticut Department of Public Health's comments on this important matter.

Sincerely, Ellen Blaschiriski, M.B.A., R.S., Chief, Regulatory Services Branch

EPA Comment Code: 6120

Comment: U.S. Environmental Protection Agency,

My name is Andrew Freed and I am writing you in regards to an issue that has been brought to my attention recently. A young lady I encountered informed me of the epidemic surrounding perchlorate in drinking water. She educated me on the concerns and factors if we do not regulate the amounts of perchlorate in our drinking water.

One of the concerns she brought up is that perchlorate contamination is a nationwide problem. Not only does this effect my drinking water personally but this concerns me because, coming from a larger family, we are spread nationwide and their health is just as important to me as my own.

Another concern is that the EPA is ignoring the fact that lower levels of perchlorate in our drinking water does have impacts on health, more than they previously thought. One of the risks is impairment to the thyroid gland. Many people aren't aware of the importance of that gland. It not only controls growth it also controls development and metabolism. When tampered with, these impacts are especially harmful to children and fetuses.

And a factor that really stuck home is the lack of concern for our nation from the EPA. In our world today, we have to start somewhere in, order to make change. Our newly appointed president wants to make change and this might be a step in the right direction. A national primary drinking water regulation is needed to protect public health. Citizens of the United States are not aware of many of the risks they face everyday. We rely on government agencies to ensure our safety when it comes to everyday exposure to things we take for granted like the water:we drink and the air we breathe.

All I am asking for is that you take a look at the concerns and think to yourself would you or your loved ones want to drink water that is contaminated?

Thank you for your time. Sincerely, Andrew Freed

To Whom It May Concern

Perchlorate is a widespread contaminate. It is a nationwide problem, that has health impacts at lower levels than previously thought. Perchlorate contamination threatens public health. Traces of Perchlorate have been detected in people, the foods we eat, and groundwater.

I am now aware the United States Environmental Protection Agency (EPA) has announced its intention not to regulate Perchlorate in drinking water. I am writing this letter to ask that the EPA reverse there decision. A national primary drinking water regulation is needed to protect public health.

Thank you. Respectfully, Dr. Edward Flok 1335 Jefferson Street Hellertown, Pa. 18055 610-838-4851 Email: eddieflok57@gmail.com

EPA Comment Code: 6120

Comment: U.S. Environmental Protection Agency,

My name is Kristin Verrastro and I am writing you in regards to the recent concerns of regulating perchlorate in our nations drinking water. I am a resident of Pennsylvania and have been recently informed about this growing problem.

I am not sure if you are aware of the dangers of the perchlorate being in our drinking water but it does not just affect a specific area. It is a nationwide problem and impacts health issues at lower levels than previously thought. One of the health problems that perchlorate can impair is the thyroid gland. As a person who deals with thyroid issues personally this has raised a red flag in my life. If you are not aware, the thyroid glad controls growth, development and metabolism, which can be extremely harmful if tampered with to children and fetuses.

Also speaking as a human being needing water to survive everyday life, the excessive amounts of perchlorate in our drinking water needs to be regulated to protect public health. I am 26 years old woman and some day would like to have children and the risk that they may become sick because of something that we as a nation could have fixed is also something that raises a red flag in my life.

All I am asking for is that you take a look at the concerns and think to your self, would you or your loved ones want to drink water that is contaminated?

Thank you for your time.

Kristin E. Verrastro

To the US Environmental Protection Agency,

You need to reverse your decision and regulate perchlorate in drinking water. Perchlorate contamination is a nationwide problem and has health effects at lower levels than previously thought. A national primary drinking water regulation is needed to protect public health. Please reconsider your decision. This is a big health issue.

The Kemmerer Family

Comment: To All Readers,

Perchlorate is a harmful chemical found in our drinking water. It is used in Rocket fuel and explosives. Every day, citizens ingest thousands of gallons nationally. If something is not done soon, This great country will be left a barren wasteland with no humans to care for it and all our efforts will have been wasted. Perchlorate can cause massive problems both physically and mentally to any human that ingests it.

Response: See response to comment code 6120.

Commenter Name: Matt Lewis

EPA Document ID: EPA-HQ-OW-2008-0692-2116
EPA Comment ID: 21967
EPA Comment Code: 6120

Comment: This country strives not on its technological booms, but the minds that drive them. If we do not act now, it'll soon be too late and what use will these technological advances be to us then. Without the bright minds of our citizens, what use is a government who wouldn't act when it had the chance.

If the EPA does not do something to prevent further problems now, then there is no point in allowing them to stay as a federal agency anymore. The EPA has a responsibility to act now and as such should proceed with all haste. No Bureaucratic procedure or code should stop them. No effort should be made to stop them from proceeding to fulfill their duty to this great country.

There are many sources of perchlorate contamination including many military bases, fireworks manufacturers, and blasting at construction sites. If there were more routine testing then perhaps the problem could be more properly identified. Currently perchlorate has been found in 37 states, and in public water systems serving over 20 million people.

Respectfully, Matt Lewis

Comment: November 6, 2008 U.S. Environmental Protection Agency

Sir / Ma'am,

It is my understanding that the EPA intends not to regulate the levels of Per chlorate in our drinking water. I urge you to reconsider this position. A standard must be set. Per chlorate is a harmful chemical that is used in rocket fuel and explosives. It should not be present in our children, or ourselves. Per chlorate affects the thyroid gland and may severely impair growth and development of fetuses and children. With this said, regulation is a must. This should not be allowed to go unmonitored. Please reconsider your position, for yourself, and our future. Thank you for your time and consideration.

Respectfully yours, Linda E. Lozier

Water Docket EPA Mailcode 2822T 1200 Pennsylvania Ave. Washington, D.C> 20460

Re: Docket ID No. EPA-HQ-OW-2008-0692

I am writing to implore you to overturn your decision regarding not regulating perchlorate in drinking water! I am a lifelong resident of Maryland and I am a holistic healthcare practitioner. Health and nutrition is a priority in my family and while I can control what we eat, I have always assumed we have safe and clean drinking water. Since I believe that perchlorate is a harmful chemical, it is the responsibility of the EPA to regulate specific levels of this chemical in our drinking water. By being proactive in this regard we shall avoid future health problems and save not only countless dollars for health care but more importantly, citizens health and well-being.

Sincerely, Katie Milleker

To the powers that be,

I write as a concerned citizen regarding perchlorate contamination. I understand that it may be present in our water supply, especially near military installations. I live in Anne Arundel Country, Md. - home to Ft. Meade, as well as mercury contamination sites. And for 35 years, I have worked in the field of early childhood disabilities.

Whatever control we may have over harmful substances in our environment is worth achieving. Please consider the safety cautions related to perchlorate contamination.

Thank you Nancy [illegible]

ATTN: Docket ID No: EPA-HQ-OW-2008-0692

As someone who trusts the Government to protect me from "The Axis of Evil", I also trust that same Government to ensure I have safe, clean drinking water available to myself and my children. I recently learned that the EPA is intending to not regulate the amount of perchlorate in drinking water, and I find that frightening.

I strongly encourage you to reconsider this decision; as it will affect my two young children. Perchlorate has been linked to mental retardation, loss of hearing and speech or deficits in motor skills in children with thyroid problems. My children are genetically predisposed to thyroid disease, so this is very worrisome for me.

We have enough to worry about in this country: terrorism, education, health care, the economy, using less oil and reducing our carbon footprints. I don't want to have to worry about the water that crosses my children's lips too.

Sincerely, Rachelle Stanley 2607 April Dawn Way Gambrills, MD 21054

Dear Fellow American,

I am writing you concerning our water supply. Among all of the other contaminates in our drinking water, there is the issue of perchlorate and I hear the EPA does not intend to regulate this chemical. It is inconceivable to me that it is not already being monitored considering how it affects thyroids, motor skills, development and other kinds of mental health. It impacts our children the most. I feel that perchlorate should be part of the mandatory testing done for our water supply. The health of all American citizens is crucial. Basically, failure to remove perchlorate's effects is consciously neglectful. We need to lock after our own welfare and be our own advocates. Monies used to protect ourselves from this chemical are just that: Monies. Our health is priceless. Please vote to make the regulation of perchlorate mandatory for all states.

Thank you for your time,

Kaii Heward

EPA Comment Code: 6120

Comment: To All Readers,

Perchlorate is a harmful chemical found in our drinking water. It is used in Rocket fuel and explosives. Every day, citizens ingest thousands of gallons nationally. If something is not done soon, This great country will be left a barren wasteland with no humans to care for it and all our efforts will have been wasted. Perchlorate can cause massive problems both physically and mentally to any human that ingests it.

Response: This is not a comment, no response necessary.

Commenter Name: Brenda Lewis
Commenter Organization:
EPA Document ID: EPA-HQ-OW-2008-0692-2191
EPA Comment ID: 22392

Comment: This country strives not on its technological booms, but the minds that drive them. If we do not act now, it'll soon be too late and what use will these technological advances be to us then. Without the bright minds of our citizens, what use is a government who wouldn't act when it had the chance.

If the EPA does not do something to prevent further problems now, then there is no point in allowing them to stay as a federal agency anymore. The EPA has a responsibility to act now and as such should proceed with all haste. No Bureaucratic procedure or code should stop them. No effort should be made to stop them from proceeding to fulfill their duty to this great country.

There are many sources of perchlorate contamination including many military bases, fireworks manufacturers, and blasting at construction sites. If there were more routine testing then perhaps the problem could be more properly identified. Currently perchlorate has been found in 37 states, and in public water systems serving over 20 million people.

Respectfully, Brenda Lewis

Comment: Docket # EPA-HQ-OW-2008-0692 Environmental Protection Agency Mailcode: 2822T, 1200 Pennsylvania Ave., NW Washington, 20460

Dear Administrator Johnson and EPA staff,

I urge you to set a drinking water standard for perchlorate. Perchlorate is found in drinking water in at least 26 states, and 20-40 million people could be exposed to this chemical. Businesses and Individuals appreciate "Standards" and "Standards for safe drinking water" is something the average U.S. citizen believes the EPA provides. They have no idea that the upmost is not being done to protect the countries supply of clean water. Do the right thing for the multitude of taxpayers who are busy making a living and raising a family. THEY TRUST that the EPA is looking out for their health - Honor their confidence in you by insuring that perchlorate is regulated throughout the U.S.A.

I urge you to reverse your decision and to set a national drinking water standard for perchlorate.

Sincerely, Dixie Walker 214 Chase Dr Pelham, AL 35124

Dear Administrator Johnson and EPA staff,

I urge you to set a drinking water standard for perchlorate. I live near Aberdeen Proving Ground and have countless friends who suffer with thyroid disease. While working on Post, I too was diagnosed with thyroid problems and took synthroid for 10 years. Once I stopped drinking that water and changed jobs, I could not get my thyroid regulated. They eventually took me off the medicine because my thyroid function was in normal ranges.

This is an important issue and warrants attention and more study.

Sincerely, anita brightman 210 archer street bel air, MD 21014

Dear Administrator Johnson and EPA staff,

Hello.

As a student of toxicology and a mother, I urge you to set a drinking water standard for perchlorate that will protect pregnant women and babies nationwide. I know you must already understand the potential health problems perchlorate can cause, so I will not lecture, but please take note of what I say.

My son is just older than newborn; tap water goes into his formula and that of many other small children that I know and do not. Their nervous systems are fragile yet as they develop; when there is even the most minute chance of harming or stunting so precious a part of them, I feel that it is cause for strict, non-discriminate regulations to be put in place concerning such potentially harmful agents.

"Perchlorate is found in drinking water in at least 26 states, and 20-40 million people could be exposed to this chemical." This statement worries me. I see my son developing, making cause-and-effect relationships, beginning to comprehend color, beginning to respond to me with smiles. It makes me feel fulfilled beyond anything else I've felt. I can't imagine how horrible it would be for a mother to look at her child and know that her baby couldn't do such things because of exposure to a harmful chemical.

I am aware that the problem of this compound's presence in drinking water is not necessarily so bad as to cause such heavy retardation in a child, but I worry about the potential for the situation to fast

become as such, thus I write to you to consider making a blanket regulation preemptively to ensure drinking water will never have harmful levels of perchlorate.

Problems are best avoided by ensuring that they can't happen to begin with. Please consider this. I urge you to. Please reverse your decision and set a national standard on perchlorate. Children are depending on us to keep them safe and healthy. Let's not make them lose their faith in us.

Sincerely, Amy Geffre 131 N Clark St Apt. B Forest City, IA 50436

Dear Administrator Johnson and EPA staff,

Perchlorate should NOT be anywhere near our nation's pregnant women, infants, children, or our drinking water supply. It's difficult to believe that this is an issue that has to be questioned, when it poses a health threat to to 20-40 million people nation wide.

When the health of young children is being put to the test, aren't we better off being SAFE than sorry?

Perchlorate poses a risk for pregnant women, newborns and young children by interfering with thyroid hormone, which is critical for optimal development of the brain and nervous system.

Today 1 in 159 children are diagnosed with autism, a disorder that is directly related to the brain and nervous system. Could there be a connection? Is it worth risking? I don't think so.

Response: See response to comment code 6120.

Dear Administrator Johnson and EPA staff,

hello.

i am curious about this disinterest in regulating national drinking water.

why wouldn't we want to continue to maintain healthy standards for our primary necessity in life?

i spent many years in quebec, and enjoyed the benefit of seeing the true sources of the water supplies to their entire city.

it's remarkable to note the difference, between florida sulphur water... carolina mountain water... new york city tap water... chicgao re-filtered lake michigan water...hawaiian lava rock filtered water, and canadian melted snow.

of course there are geographic differences that create natural filtration variances, but why should we be sacrificing anything when it comes to keeping our water clean?

we are capable of doing great things. we have boundless technology, and plenty of educated people looking to work...

why not set a noble task, and pursue excellent standards?

Perchlorate does not sound like a natural part of H20. and since my tap water does not come with a list of ingredients, save for a once a year particulate analysis, i would really prefer to know the EPA was doing a fine job keeping an eye on what was coming into my glass.

the japanese are doing incredible things with water filtration. and as i have said, i was also very impressed with the great effort the canadians have put into protecting the pristine sources of their drinking water.

why shouldn't we take pride in a precious commodity? last i heard, it was a costly item in jordan, where people were standing in line to get a limited amount of clean bottled water issued to them.

and we painfully pollute, and waste...when we have the ability to improve.

again, I urge you to reverse your decision and to set a national drinking water standard for perchlorate, and to raise our standards overall.

clean water is a deciding factor for where i choose to live in this world. it's amazing to think that it is something the EPA could possibly be taking for granted. thank you.

Re: Docket ID No. EPA-HQ-OW-2008-0692

Dear Environmental Protection Agency:

I am writing to urge, beg and even cajole you to set a federal limit for percholate in drinking water. Percholate is a nationwide probmem with significant health impacts. While I am fortunate enough to be able to afford to pay money to filter my drinking water, I believe that clean drinking water is a fundamental right of every American, including those who cannot afford to spend extra money to obtain it. Please regulate percholate. We will be a healthier, wealthier and wiser nation for your efforts.

With kind regards, Heidi Mayor

I learned there is a horrible chemical in our world. This chemical is called Perchlorate. Perchlorate can affect the thyroid gland, which controls growth, development and metabolism. This is very harmful to children and babies. This chemical has been found in 37 states. Therefore, WE NEED TO KEEP PERCHLORATE OUT OF DRINKING WATER!!!!!! Please help us keep our water safe by keeping Perchlorate out of our drinking water!

Sincerely, [comment from patron under the age of 13]

Comment: Dear Department of Environmental Protection,

As an uncle of 13 children and a father-to-be I find it at the minimum troubling, and at most a travesty of justice that your body has decided not to regulate perchlorate in drinking water. It has been brought to my attention that even low levels of this chemical can have adverse health effects. The lack of care and disregard for what is right, good, and just, I find personally appalling. I propose that you and your body seriously reexamine your policies and your morals. I thank you for your time and courtesy in hearing me voice my complaints. I trust that in the end you will make the right decision.

Yours truly, Joseph [illegible] M.D.

Environmental Protection Avenue NW Washington DC 20460

Re: Docket EPA-HQ-OW-2008-0692 Drinking Water Preliminary Regulatory Determination

This letter is to request that your agency set a drinking water standard for perchlorate, consistent with the legislation endorsed by the Senate Environment and Public Works Committee, and that you monitor levels of the chemical in tap water.

Perchlorate is a chemical in rocket fuel that has been linked to thyroid problems in pregnant women, newborns and young children. The maximum safe level now established in drinking water is 15 times higher than what the EPA declared safe in 2002. Under this new standard, more than 16 million Americans would be exposed to unsafe levels of perchlorate in their drinking water, placing more than 16 million Americans at risk. Perchlorate has been found in the drinking water in 35 states in the U.S.

I hope you will set a federal standard establishing safe levels for perchlorate in drinking water and will make provision for monitoring which will assure that Americans can be assured their drinking water is free from this dangerous chemical.

Sincerely, Avis Rana

Comment: I support EPA including Perchlorate on the National Primary Drinking Water List. I am especially concerned that it is not included to date as a pregnant woman. Small changes in maternal thyroid hormone levels during pregnancy have been associated with reduced IQs in children and high levels of perchlorate in the water could lead to mental retardation in children of mothers who consumed contaminated water. This is not just a health concern for fetuses and infants, but for anyone in our country suffering any kind of thyroid problems. Which considering how unhealthy Americans are, there are probably plenty of people who suffer from thyroid issues. Perchlorate allowed in the drinking water will only decrease the health of our population.

California has already taken steps to regulate this contaminant, EPA should too. EPA guideline of 1 part per billion for its public drinking water standard should be enforceable, not just a recommendation. EPA should be protecting human health and the environment, not industry. I sincerely hope and pray that EPA will go back to its mission statement and ignore industry influences. Fight for us and the environment, regulate Perchlorate in the drinking water today!

Response: See response to comment code 6120.

Comment: d. EPA should regulate all exposures from these types of chemicals as we know little about the harm they cause when exposed to or mixed with different medicines or the multiple other chemicals in our bodies or in individual water systems. Because there is not enough data about our exposures to these chemical "soups" to assure protection for the American people and until there is more data assuring our safety from mixing perchlorates with other drugs and chemicals, EPA should aim to control all exposure.

Response: See response to comment code 6120.

EPA Comment ID: 28370
EPA Comment Code: 6120

Comment: I very urgently ask the U.S. Environmental Protection Agency to move forward with a drinking water standard of no higher than 1 part per billion for perchlorate.

Perchlorate contamination is a nationwide problem and has health impacts at far lower levels than previously thought; without this protection, infants and children will be damaged.

Perchlorate in concentrations above 1 PPB will impair the thyroid gland, which controls growth, development and metabolism. Developing fetuses, infants and children with thyroid impairment will suffer mental retardation, loss of hearing and speech and deficits in motor skills.

A national primary drinking water regulation at 1 PPB for perchlorate is absolutely essential to protect public health.

Do not delay adopting this essential limit for perchlorate.

Sincerely, Dr. Joe Parrish US Environmental Watch 300 E. 56th Street Suite 2B New York, NY 10022

Comment: I am a program organizer for NJ Environmental Federation as well as a mom and grandmother.

My deep concern about perchlorate in our waterways is growing. Particularly in regards to NJ which is now becoming a superfort by combining FT Dix, Mcquire Air Force Base and Lakehurst Navel Air Station. As a results, military air traffic has increased from 8000 to 80,000 over Centerl Jersey, which is home to the headwaters of the Metedeconk and Toms River and the Kirkwood Cohansey aquifer that supply most of the drinking water for central and South Jersey. Added to that, this area is less than 50 miles in any direction from a major commercial airport.

Setting standards for perchlorate at one part per billion is the only reasonable action that can be taken protect the children and residents of this area. Sadly you may be too late.

Comment: Gentlemen;

I have read for a number of years about the infiltration of perchlorate mostly from some federal (or Federal contractor) facilities through ground water or other discharges into surface waters. Perchlorate contamination is found (for example) in the Colorado River system and in irrigation and

domestic water supplies drawing on it. Many of the California vegetables which millions of Americans enjoy have some perchlorate contamination. People with some knowledge of chemistry often assume that perchlorate is, like sulfate, fairly inert and innocuous at low concentrations. However, I understand that there is evidence that perchlorate has effects on thyroid health, even at sub-ppm concentrations, and it is known that its bromine analog, bromate, is to be avoided due to its toxic effects at low concentrations (one of the reasons that ozonation is not a viable drinking water treatment when bromide ion is present). For these reasons, and because the sources of perchlorate contamination are fairly limited, I would ask that EPA begin to regulate this chemical more stringently in discharges and in drinking water supplies, perhaps down to the 1 ppb level in the latter. Thank you for your consideration of this opinion.

Comment: I urge the U.S. Environmental Protection Agency to move forward with a drinking water standard of no higher than 1 part per billion for perchlorate.

Perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought; protecting infants and children is critical.

a national primary drinking water regulation would provide a meaningful opportunity to protect public health.

5 years ago, I developed hypothyroidism. There is no family history of this. I know many others. I can't help but wonder if perchlorate in the water used to grow vegetables in the western U.S. states is partly responsible. At age 51, the health concerns for me are nothing compared to those of children exposed to this. Please take action to help protect our health. Thank You.

Comment: I urge you to set regulations banning perchlorate of concentrations higher than 1 part per billion in drinking water. Perchlorate (even in small amounts) is linked to thyroid damage, which, in fetuses and children, can lead to intelligence disability (mental retardation), loss of hearing and speech, or motor impairment. It is unconscionable to allow the levels or perchlorate in drinking water to go unpunished and untreated.

Response: See response to comment code 6120.

Comment: On August 19, the U.S. Environmental Protection Agency (EPA) requested public comments related to setting a limit for perchlorate in drinking water. Last year EPA appeared poised to announce that it would not set a limit but is now reviewing scientific and other information to make a decision about moving forward with a regulation now.

Why limit perchlorate. It is a harmful chemical that EPA claims has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher.

Perchlorate, even in small amounts, can impair the thyroid gland, which controls growth, development and metabolism.

Developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills.

I urge the U.S. Environmental Protection Agency to move forward with a drinking water standard of no higher than 1 part per billion for perchlorate.

Response: See response to comment code 6120.

Attachment

September 4, 2009

Mr. Eric Burneson Office of Ground Water and Drinking Water Standards and Risks Management Division Environmental Protection Agency 1200 Pennsylvania Avenue, NW, Mailcode 2822T Washington, D.C. 20460

Re: Docket ID No. EPA-HQ-OW-2009-0297

Dear Mr. Burneson,

On behalf of our various organizations and our tens of thousands of members throughout the United States, we are writing to express our belief that the potential health impacts from exposure to perchlorate through drinking water are significant and that they warrant prompt regulation to protect public health and safety. Setting a drinking water standard will provide the U.S. Environmental Protection Agency (EPA) with a "meaningful opportunity for health risk reduction for persons served by public water systems." Consequently, EPA should move as quickly as possible to establish a more protective reference dose for perchlorate and then to promulgate a maximum contaminant level (MCL) for perchlorate that is no higher than one part per billion (ppb). We base this view on the scope of the contamination in drinking water supplies, exposure of the American population through other pathways, including food, and the most recent scientific studies that demonstrate serious health threats, even at low levels, to a larger portion of the population than previously recognized. These studies are based upon a much larger exposure data set than the studies upon which the current reference dose, and thus the entire regulatory regime, is based.

Response: Regarding "establishing a more protective reference dose for perchlorate," see response to comment code 2110. Regarding EPA's decision to regulate perchlorate, see response to comment code 6120.

EPA Comment Code: 6120

Comment: A perchlorate drinking water standard of no higher than 1 ppb would protect a large share of the American population currently at risk. Given the scope of the perchlorate contamination nationally, the multiple exposure pathways and other environmental contaminants impacting thyroid function and development, and the data demonstrating a serious health threat to a significant part of the country's population, EPA is obligated to establish such a drinking water standard. We applaud the agency's consideration of how to move forward to regulate this contaminant and urge you to take steps to establish a protective MCL as soon as possible.

Sincerely,

Mr. Eric Burneson Office of Ground Water and Drinking Water Standards and Risks Management Division Environmental Protection Agency 1200 Pennsylvania Avenue, NW, Mailcode 2822T Washington, D.C. 20460 Re: Docket ID No. EPA-HQ-OW-2009-0297

Dear Mr. Burneson,

On behalf of The Alliance of Nurses for Healthy Environments, we are writing to express our belief that the potential health impacts from exposure to perchlorate through drinking water are significant and that they call for prompt regulation to protect the public's health and safety. Setting a drinking water standard will provide the U.S. Environmental Protection Agency (EPA) with a "meaningful opportunity for health risk reduction for persons served by public water systems". EPA should move as quickly as possible to establish a more protective reference dose for perchlorate and then to promulgate a maximum contaminant level (MCL) for perchlorate that is no higher than one part per billion (ppb).

Response: See response to comment code 6120.

Comment: I urge the EPA to adopt a limit of 1 PPBW perchlorate in U.S. drinking water. I understand recent studies show perchlorate to be more harmful than previously thought, especially to infants and young children. It may cause mental retardation, loss of hearing and speech, and poor development of motor skills.

EPA's own data show perchlorate to be present in drinking water in 37 states, including public water systems serving more than 20 million people.

I understand that perchlorate, like any harmful chemical, probably affects different people to different degrees, but I also believe the EPA should err on the conservative side until more data can be amassed regarding the effects of these chemicals on a decent statistical basis. Big business will always have powerful advocates and lobbyists presenting gloomy scenarios of high costs and dubious benefits, but who advocates for the average guy here in the U.S.?

Comment: It is imperative that our drinking water be protected in every possible way. It us unconsciensionable that perchlorate would be allowed to enter it, and unconsciensionable of an industry to seek to be able to place the compound in ground water. Please issue the appropriate regulation to disallow perchlorate from being placed into our water supplies.

Response: Perchlorate is not being placed into water systems. EPA has decided to regulate perchlorate. See response to comment code 6120.

Comment: Dear Trusted employees at Environmental Protection Agency of the USA,

The citizens of this country trust you to analyze every single substance that comes at all in contact with our living environment, and to determine what amounts we can tolerate and still be healthy. We, including industry, needs to know that, so we can act accordingly.In your spare time you need to do that. But since you don't have any spare time ... then prioritize! and do the ones that are obvious first!

Perchlorate is one of the very obvious ones that need to be done now! And please remember, that if you wait till a chemical is at the top of the priority list, then your analysis is more likely to be tainted by politics or industry pressures. It's better to get it done early, while no one is paying attention, so you can make a true impact analysis .... and please, always err on the side of human safety .... better to be safe than sorry. Thanks kindly ... we're counting on you to protect us. Eva in Denver, CO

Comment: I urge the U.S. Environmental Protection Agency to move forward with a primary drinking water standard for perchlorate that prioritizes potential and proven risks to public health and ecosystems over risks to industries that use perchlorate.

Perchlorate is a harmful chemical that EPA claims has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher. Perchlorate, even in small amounts, can impair the thyroid gland, which controls growth, development and metabolism. Developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills.

Comment: I am an environmental protection science/chemistry graduate, and I constantly argued with professors, guests from ALCOSAN in Pittsburgh and everyone else that would listen about chemical levels in water and what was acceptable in drinking water. Water is essential to all life, and there should not be an acceptable level of rocket fuel in water. There should be NO rocket fuel, or PCBs or heavy metals, etc., in our water. The water authorities should not have to super- chlorinate our water, like it is in Pittsburgh, to give us something that is essential to our life. Stand up and be the Environmental Protection Agency, and not the Chemical Subsidiaries Protection Agency. You were supposed to be on our side. How many cancer deaths do we have in the US, compared to 30 or 50 years ago? Clean air and water is necessary, not optional. We are paying you, and this is what we want.

Thank you for your time,

Ryan Tomazin Bridgeville, PA

Administrator Jackson USEPA Headquarters Ariel Rios Building 1200 Pennsylvania Avenue, N. W. Washington, DC 20460

September 18, 2009

Dear Administrator Jackson,

I am writing, on behalf of Food and Water Watch, to urge you to make a national primary drinking water rule for perchlorate.

Response: See response to comment code 6120.

Commenter Name: Kathy Dolan
Commenter Organization: Food and Water Watch (FWW)

EPA Document ID: EPA-HQ-OW-2009-0297-0526
EPA Comment ID: 28612
EPA Comment Code: 6120

Comment: The widespread exposure of the population to some level of perchlorate raises serious health concerns. Perchlorate can inhibit the thyroid glands iodine uptake, potentially leading to hypothyroidism. Severe hypothyroidism during pregnancy can lead to abnormal fetal cognitive development, and even mild hypothyroidism during pregnancy is associated with subtle cognitive defects in children. Thus, perchlorate could alter fetal brain development, having lifelong cognitive effects for those affected.

EPA's failure to regulate perchlorate in drinking water places consumers, especially children and pregnant women, at risk. We urge the EPA to consider the regulation of perchlorate as an opportunity to protect our waterways and make our drinking water safe for all.

Sincerely,

Kathleen Dolan Triclosan Campaign Advocate

Comment: Administrator Jackson USEPA Headquarters Ariel Rios Building 1200 Pennsylvania Avenue, N. W. Washington, DC 20460

September 18, 2009

Dear Administrator Jackson,

I am writing, on behalf of Food and Water Watch, to urge you to make a national primary drinking water rule for perchlorate.

Perchlorate has been found in the drinking water supply of 35 states and the District of Columbia. Widespread human exposure to perchlorate was confirmed by the Center for Disease Control's NHANES study, which found that 100 percent of the 2,820 randomly selected study participants had detectable levels of perchlorate in their urine. And according to your request for comment notice, dated August 5, 2009, the number of people served by water contaminated with high levels of perchlorate ranges between 53.4 and 16.8 million people.

Response: See response to comment code 6120.

Commenter Name: Apparent Mass Mailing #11 - Food and Water Watch
EPA Document ID: EPA-HQ-OW-2009-0297-0526
EPA Comment ID: 28618
EPA Comment Code: 6120

Comment: The widespread exposure of the population to some level of perchlorate raises serious health concerns. Perchlorate can inhibit the thyroid glands iodine uptake, potentially leading to hypothyroidism. Severe hypothyroidism during pregnancy can lead to abnormal fetal cognitive development, and even mild hypothyroidism during pregnancy is associated with subtle cognitive defects in children. Thus, perchlorate could alter fetal brain development, having lifelong cognitive effects for those affected.

EPA's failure to regulate perchlorate in drinking water places consumers, especially children and pregnant women, at risk. We urge the EPA to consider the regulation of perchlorate as an opportunity to protect our waterways and make our drinking water safe for all.

Commenter Name: Mic Stewart
Commenter Organization: Water Quality Section, Metropolitan Water District of Southern California
EPA Document ID: EPA-HQ-OW-2009-0297-0496
EPA Comment ID: 28710
EPA Comment Code: 6120

Comment: Metropolitan's Concerns

Perchlorate contamination entering the Colorado River from the Las Vegas Wash area represents the largest extent of perchlorate contamination in the country. Water from the Colorado River downstream of the Las Vegas Wash supplies drinking water for over 23 million people throughout Nevada, California, and Arizona. Any effort to regulate perchlorate would ensure some degree of public health protection for this source of water supply. Metropolitan believes that federal regulation of perchlorate would provide a meaningful opportunity for health risk reduction for the public water systems as described in the Safe Drinking Water Act.

Response: See response to comment code 6120.

Commenter Name: Mic Stewart
Commenter Organization: Water Quality Section, Metropolitan Water District of Southern California
EPA Document ID: EPA-HQ-OW-2009-0297-0496
EPA Comment ID: 28714
EPA Comment Code: 6120

Comment: Since the 1996 amendments to the Safe Drinking Water Act, no new contaminant has met EPA's three criteria for national primary drinking water regulation. Metropolitan believes that a determination by EPA not to regulate perchlorate in drinking water could adversely influence cleanup efforts along the Colorado River and other contaminated sites.

Metropolitan appreciates this opportunity to provide comments on scientific approaches to analyzing scientific data related to perchlorate in drinking water and requests that EPA carefully consider these comments. Please contact me at (213) 217-5696 if you have any questions, or if I can provide additional information.

Very truly yours, Mic Stewart, Ph. D. Manager, Water Quality Section

Response: See response to comment code 6120.

Commenter Name: Nsedu O. Witherspoon
Commenter Organization: Children's Environmental Health Network
EPA Document ID: EPA-HQ-OW-2009-0297-0674
EPA Comment ID: 28737
EPA Comment Code: 6120

Comment: The Network believes that the potential health impacts from exposure to perchlorate through drinking water are significant and that they warrant prompt regulation to protect public health and safety. Setting a drinking water standard will provide the U.S. Environmental Protection Agency (EPA) with a "meaningful opportunity for health risk reduction for persons served by public water systems".

Consequently, EPA should move as quickly as possible to establish a more protective reference dose for perchlorate and then to promulgate a maximum contaminant level (MCL) for perchlorate that is no higher than one part per billion (ppb). We base this view on the scope of the contamination in drinking water supplies, exposure of the American population through other pathways, including food, and the most recent scientific studies that demonstrate serious health threats, even at low levels, to a larger portion of the population than previously recognized. These studies are based upon a much larger exposure data set than the studies upon which the current reference dose, and thus the entire regulatory regime, is based.

Perchlorate has been found in more than 400 drinking water sources in 26 states, potentially affecting tens of millions of people. EPA's own data say that nearly 17 million people receive their water from public water systems where perchlorate has been found at levels exceeding 4 ppb. Were sampling routinely conducted with a detection limit of 1 ppb, that number would be much higher-

particularly considering the estimated 20 million people in the Southwest who receive drinking water from the Colorado River.

Response: See response to comment code 6120.

Commenter Name: Nsedu O. Witherspoon
Commenter Organization: Children's Environmental Health Network
EPA Document ID: EPA-HQ-OW-2009-0297-0674
EPA Comment ID: 28742
EPA Comment Code: 6120

Comment: A perchlorate drinking water standard of no higher than 1 ppb would protect a large share of the American population currently at risk. Given the scope of the perchlorate contamination nationally, the multiple exposure pathways and other environmental contaminants impacting thyroid function and development, and the data demonstrating a serious health threat to a significant part of the country's population, EPA is obligated to establish such a drinking water standard. We applaud the agency's consideration of how to move forward to regulate this contaminant and urge you to take steps to establish a protective MCL as soon as possible.

Sincerely,

Nsedu O. Witherspoon, MPH Executive Director

Comment: I urge the U.S. Environmental Protection Agency to move forward with a drinking water standard of no higher than 1 part per billion for perchlorate.

perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought; protecting infants and children is critical.a national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Although I am not sure if 1 ppb (part per billion) is a realistic level, the current level of air travel is only increasing warranting serious review of safe levels. We owe it to our children (and their's) to, at the very least, set a realistic regulatory level that is 1.) not cost-prohibitive, 2.) safe and 3.) maintainable.

Thank you for attention to this matter.

Comment: I urge the U.S. Environmental Protection Agency to move forward with a drinking water standard of no higher than 1 part per billion for perchlorate. * perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought; protecting infants and children is critical. * a national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Recently, a defense analysis postulates that the world will be competing for water resources. in the light of this we cannot afford to further pollute our sources of fresh water with any more chemicals. Further we must hold the polluters responsible for any cleanup of known harmful chemicals in our water supplies.

Comment: However, the U.S. Environmental Protection Agency (EPA) has still not decided whether to set a drinking water standard - a limit - for perchlorate, an ingredient in rocket fuel that is contaminating water nationwide.

Clean Water Action members can help make sure the EPA takes action to limit perchlorate in drinking water.

On August 19, the U.S. Environmental Protection Agency (EPA) requested public comments related to setting a limit for perchlorate in drinking water. Last year EPA appeared poised to announce that it would not set a limit but is now reviewing scientific and other information to make a decision about moving forward with a regulation now.

Why limit perchlorate?

Perchlorate is a harmful chemical that EPA claims has been found in 395 sites in 37 states, including 153 public water systems serving over 20 million people. Some estimates are even higher.

Perchlorate, even in small amounts, can impair the thyroid gland, which controls growth, development and metabolism.

Developing fetuses, infants and children with thyroid impairment may suffer mental retardation, loss of hearing and speech or deficits in motor skills.

Sample Letter

I urge the U.S. Environmental Protection Agency to move forward with a drinking water standard of no higher than 1 part per billion for perchlorate.

perchlorate contamination is a nationwide problem and has health impacts at lower levels than previously thought; protecting infants and children is critical.a national primary drinking water regulation would provide a meaningful opportunity to protect public health.

Comment: From 1962-1977, I was raised in West Covina, California, a city whose drinking water supply was later determined to be contaiminiated by perchlorate. In late 1977, after I left for college, I was diagnosed with thyroid disease. The disease made it very difficult to pursue my studies, forcing me to drop classes. It also significantly intefered with my social integration during my freshman year. When later I learned about the contamination of the water supply in West Covina, I was angry to think how that might have contributed to the disease. It wrecked my life for the period leading up to diagnosis and treatment. I'm still concerned about the longterm health effects. Please strictly regulate this chemical in our drinking water.

U.S. Environmental Protection Agency Office of Water Docket (Mailcode: 2822T) 1200 Pennsylvania Avenue, NW Washington, DC 20460

Submitted via www.regulations.gov

Comments from the NATURAL RESOURCES DEFENSE COUNCIL

on the Drinking Water: Perchlorate Supplemental Request for Comments

Docket EPA-HQ-OW-2009-0297 Federal Register / Vol. 74, No. 159/ Wednesday, August 19, 2009

SUMMARY

On August 19, 2009, the U.S. Environmental Protection Agency (EPA) issued a Federal Register (FR) notice[FN1: 74 Fed. Reg. 41883 (August 19, 2009).] requesting comments on additional approaches to analyzing data related to its perchlorate preliminary determination as detailed in its October 10, 2008 FR Notice.[FN2: 73 Fed. Reg. 60262 (October 10, 2008).] In that previous notice, EPA made a preliminary regulatory determination not to set a health-protective standard for perchlorate in drinking water.[FN3: Id.] It stated, "The Agency has determined that a national primary drinking water regulation (NPDWR) for perchlorate would not present 'a meaningful opportunity for health risk reduction for persons served by public water systems.'" EPA also proposed a health reference level (HRL) of 15 parts per billion (ppb) as the maximum contamination level of perchlorate that could be in drinking water and still keep daily human consumption levels from exceeding the reference dose (RfD) of 0.7 ug/kg/day.

In response to the October 10, 2008 FR notice, NRDC provided comments to EPA concluding that EPA's determination was legally flawed. EPA must regulate a contaminant if it may have an adverse effect on human health, if it is known to occur (or there is a substantial likelihood that the contaminant will occur) in public water systems with a frequency and at levels of public health concern; and if its regulation would present a meaningful opportunity for health risk reduction for persons served by public water systems.[FN4: 42 U.S.C. [Sec] 300g-1(b)(1)(A).] For perchlorate, each of these three requirements are met, and therefore, underscore the need for EPA to regulate its presence in drinking water. First, EPA's preliminary regulatory determination acknowledges that perchlorate may adversely affect human health.[FN5: 73 Fed. Reg. 60275 (Oct. 10, 2008).] Second, as explained in more detail below, despite EPA's contention, perchlorate is known to contaminate the drinking water systems serving millions of people at levels where adverse human health effects occur. And third, setting an appropriately stringent MCL will lead to lower levels of perchlorate ingested by hundreds of thousands of infants, children, and pregnant women, thereby offering a concrete and meaningful reduction in human health risks.

The U.S. population is about 300 million people with about 6.8%, or 20 million, under 5 years old. Therefore, based on EPA estimates that 16.6 million people are served by public water system with at least one detection of perchlorate over 4 ppb, there are, therefore, likely more than one million children in each year of life (from zero to five) who may be exposed to perchlorate levels that may adversely affect their health.[FN6: This value is derived by multiplying 16.6 million by 0.068. Please see below for further explanation about the appropriate perchlorate level to set for the health reference level.] Thus, the evidentiary record does not support EPA's proposed determination. Rather, the evidentiary record makes clear that regulating these exposures do represent "a meaningful opportunity for health risk reduction for persons served by public water systems."

Based upon the evidence in the record, as discussed in greater detail below, NRDC urges EPA to reverse course, and set a national primary drinking water standard for perchlorate that is protective of sensitive sub-populations. EPA should not set a HRL at 15 ppb; rather, given the most current data available, NRDC believes that to truly protect the public health, EPA should set an enforceable maximum contaminant level (MCL) as authorized by the Safe Drinking Water Act below 1 ppb.

Response: See response to comment code 6120.

Commenter Name: Jennifer Sass
Commenter Organization: Natural Resources Defense Council (NRDC)
EPA Document ID: EPA-HQ-OW-2009-0297-0412
EPA Comment ID: 28796
EPA Comment Code: 6120

Comment: NRDC strongly objected to EPA's preliminary determination not to regulate perchlorate because the conclusions are not based on a comprehensive review of the best available science (as explained in more detail below) and are not supported by the PBPK model findings, or by EPA's expert scientific advisors on the Children's Health Protection Advisory Committee.[FN23: Letter from Melanie Marty to Administrator Johnson regarding Preliminary Regulatory Determination on Perchlorate (November 3, 2008, PDF) http://yosemite.epa.gov/ochp/ochpweb.nsf/content/perchlorateletter.htm/$file/PerchlorateLetter.pdf] In fact, drinking water that is contaminated with perchlorate at the proposed HRL of 15 ppb would leave infants and young children exposed to excessive and unsafe levels of this toxic chemical.

Response: See response to comment ID 20988 under comment code 6120.

Comment: ADDITIONAL COMMENTS

Regulating Perchlorate Represents a Meaningful Opportunity for Health Risk Reduction

NRDC notes that there is enough information for the Agency to make a final regulatory determination to promulgate a national primary drinking water standard for perchlorate. The evidence about the impact of perchlorate contaminated drinking water shows that it satisfies the requirements for promulgating a drinking water standard under the Safe Drinking Water Act: (1) perchlorate is know to have an adverse effect on the health of persons; (2) perchlorate is known to occur in public water systems with a frequency and at levels of public health concern, and (3) regulating perchlorate presents a meaningful opportunity for health risk reduction for persons served by public water systems. Therefore, EPA should set an MCL for perchlorate, rather than focus on setting an HRL.

In its October 10, 2008 preliminary determination not to regulate perchlorate, EPA acknowledged that perchlorate could have an adverse effect on human health.[FN65: 73 Fed. Ref. at 60275.] Second, based on just quarterly or semi- annual sampling along, EPA showed that 4 percent of drinking water systems have detections of perchlorate over 4 ppb. As explained in further detail below, this occurrence exposes hundreds of thousands of pregnant women, children, and infants to dangerous levels of perchlorate, giving rise to a public health concern.

In October, 2008, EPA determined that up to 28,000 pregnant women would be exposed to more than 15 ppb of perchlorate. However, at that time, EPA stated that reducing the risk that 28,000 pregnant women would be exposed to perchlorate would not provide a meaningful opportunity to reduce health risks.

What that October 2008 announcement failed to explain is that EPA's own staff experts have provided data to show that at the proposed HRL of 15 ppb, infants and children would consume perchlorate on a daily basis that exceeded the reference dose.

As explained above, EPA's proposed model shows that there are over one million children under 5 years old who would exceed the daily reference dose; this is likely an underestimate of the highly exposed.

As noted above, NRDC believes that any amount of perchlorate in drinking water over 1 ppb may have adverse health impacts on vulnerable populations, meaning EPA's estimate of the number of pregnant women who would be exposed to excessive perchlorate would be much higher than 28,000. In fact, based on EPA's estimate, over 200,000 pregnant women could be exposed to perchlorate contamination over 4 ppb (the maximum detection limit identified in EPA's estimates). As such, by any measure, a regulation that could protect up to over 200,000 pregnant women and a million children and infants would give rise to a meaningful opportunity to protect public health.

Response: See response to comment code 6120.

Commenter Name: Jennifer Sass
Commenter Organization: Natural Resources Defense Council (NRDC)
EPA Document ID: EPA-HQ-OW-2009-0297-0412
EPA Comment ID: 28816
EPA Comment Code: 6120

Comment: CONCLUSION

EPA should amend its preliminary determination on perchlorate. EPA should determine to promulgate a national primary drinking water standard for perchlorate, to protect public health. Existing data on perchlorate exposure and effects, especially on vulnerable subpopulations, demonstrates that setting a national primary drinking water standard for perchlorate would provide a meaningful opportunity for health risk reduction. EPA is therefore required to set such a standard under the Safe Drinking Water Act.

Furthermore, a maximum contaminant level below 1 ppb would afford reasonable protections to the health of the susceptible populations of pregnant women and breast-fed infants.

Water Docket Environmental Protection Agency Mail Code: 2822T 1200 Pennsylvania Ave, NW Washington, DC 20460 RE: Docket ID No. EPA-HQ-OW-2009-0297

To Whom It May Concern:

Thank you for the opportunity to provide comments on USEPA's notice, "Drinking Water: Perchlorate Supplemental Request for Comments," which was published in the Federal Register of August 18, 2009 (74 Fed. Reg. 41883-41893). On March 16, 2009, the New Jersey Department of Environmental Protection (NJDEP) proposed a drinking water Maximum Contaminant Level (MCL) of 5 ug/L, including monitoring and compliance determination requirements, in accordance with the 2005 recommendation of the New Jersey Drinking Water Quality Institute (NJDWQI), a legislatively created advisory body. The NJDEP believes that having an MCL for perchlorate will be beneficial to public health both in New Jersey and in the country as a whole.

In comments submitted on November 10, 2008, we urged USEPA to reconsider its October 10, 2008 proposed determination to not regulate perchlorate in drinking water. Our comments stressed that USEPA's proposed Health Reference Level (HRL) of 15 ug/L is not protective of infants, who are a sensitive population for perchlorate's effects on thyroid function. We also commented that the occurrence analysis presented was flawed because its use of an inappropriately high concentration, 15 ug/L, greatly reduced the size of the population predicted to be exposed at levels of public health concern. We commend USEPA for its current decision to reconsider its proposal not to regulate perchlorate, based on the comments submitted by us and by many others.

Response: This is not a comment, a response is not necessary.

Comment: Attached are EWG's comments on Docket ID no. EPA-HQ-OW-2009-0297 (Drinking Water: Perchlorate Supplemental Request for Comments). Thank you.

September 18, 2009

Mr. Eric Burneson Office of Ground Water and Drinking Water Standards and Risk Management Division Environmental Protection Agency 1200 Pennsylvania Avenue, NW Washington, DC 20460

Re: Docket ID no. EPA-HQ-OW-2009-0297

Dear Mr. Burneson:

The Environmental Working Group (EWG) strongly supports the Environmental Protection Agency (EPA) establishing a drinking water standard for the rocket fuel ingredient perchlorate. This compound contaminates drinking water supplies nationwide at levels of concern for human health, providing the agency with a meaningful opportunity for human health risk reduction through a national primary drinking water rule:

- The EPA has reported finding perchlorate, a potent thyroid toxin, in public water systems in 28 states and territories and estimated that nearly 17 million people may be served by public water systems with at least one perchlorate detection > 4 ppb - The Centers for Disease Control and Prevention (CDC) have found perchlorate in the urine of nearly 3,000 Americans who were tested as part of a national biomonitoring study, indicating widespread exposure among the U.S.

population (Blount et al 2006a) - In infants and children, drinking perchlorate contaminated tap water can result in cumulative exposures that exceed the EPA's reference dose (RfD), even at tap water concentrations as low as 1 part per billion (ppb).

Recommendations

- EPA's own analyses show that infants under six months of age are exposed to enough perchlorate via food that additional exposure to perchlorate via tap water concentrations as low as 1 ppb can result in combined exposures that exceed the RfD. To protect these highly vulnerable individuals, EPA must set an MCL of less than 1 ppb for perchlorate in drinking water.

Response: See response to comment code 6120.

Commenter Name: Anila Jacob
Commenter Organization: Environmental Working Group (EWG)
EPA Document ID: EPA-HQ-OW-2009-0297-0499
EPA Comment ID: 28937
EPA Comment Code: 6120

Comment: Summary: There is a wealth of evidence from government and academic scientists that strongly suggests that infants and children not only have disproportionately high perchlorate exposure compared with adults, they are also more vulnerable to its toxic effects. Baseline perchlorate contamination of breast milk, powdered infant formula, and commonly consumed foods and beverages ensures that almost every infant and child in the U.S. will have multiple, daily sources of perchlorate exposure during critical periods of growth and brain development. However, for those children who live in states with perchlorate contamination of tap water, the additional exposure from the tap water can easily lead to cumulative exposures that exceed the agency's RfD. A decision by the agency to set an enforceable maximum contaminant level (MCL) of less than 1 ppb could benefit the health of millions of infants and children by decreasing cumulative perchlorate exposures.

Sincerely, Anila Jacob, M.D., M.P.H. Senior Scientist

Comment: from Washington Post article

Last month, The Washington Post reported that White House officials had extensively edited the EPA's perchlorate rule-making documentation to remove scientific data highlighting some of the risks associated with the chemical, which has been found in water in 35 states. The Defense Department and Pentagon contractors who face legal liability stemming from rocket fuel contamination have lobbied for six years to avoid a federal drinking-water standard for perchlorate.

http://www.washingtonpost.com/wp- dyn/content/article/2008/10/03/AR2008100303280.html?nav=rss_business/government

This appears to be not only a medical but a political-moral issue.

Response: Please see the response to comment code 6110. EPA has reversed its October 2008 preliminary determination not to regulate perchlorate based upon a more direct evaluation of exposure to infants and developing children. In making today's final regulatory determination, EPA uses the criteria mandated by the 1996 SDWA Amendments. EPA has made its determination based upon a consideration of the best available peer reviewed science and data collected in accordance with accepted methods.

Commenter Organization:
EPA Document ID: EPA-HQ-OW-2008-0692-0370
EPA Comment ID: 19844
EPA Comment Code: 6125

Comment: The Washington Post reported that "The GAO, which produced a 2005 report calling for a better federal tracking system for perchlorate, found that limited EPA data show the chemical compound has polluted the soil, groundwater and drinking water in 35 states and the District and has contaminated 153 public water systems in 26 states." The fact that there are some infants and toddlers in this country who drink formula using water contaminated by perchlorate is sinful. I have thyroid disease. I know how sluggish and foggy my mind becomes. I know how hard this disease is to diagnose.

We spend so many dollars on the military and "homeland security" to keep Americans "safe" from enemies. This perchlorate story is an example of the enemy within. The Washington Post also reports that, "A National Academy of Sciences panel prepared a risk analysis in 2005 that...came

under attack because two of the committee's members had financial ties to defense contractors that face legal liability because of perchlorate disposal." It seems to me that military contractors run this country. We know they hand out big bucks to decision makers to prevent creating regulation requiring them to clean up the mess they make.

Response: Please see the response to comment code 6110. EPA has reversed its October 2008 preliminary determination not to regulate perchlorate based upon a more direct evaluation of exposure to infants and developing children. In making today's final regulatory determination, EPA uses the criteria mandated by the 1996 SDWA Amendments. EPA has made its determination based upon a consideration of the best available peer reviewed science and data collected in accordance with accepted methods.

EPA Comment ID: 20759
EPA Comment Code: 6125

Comment: As reported in the Washington Post on September 22, 2008:

In the EPA's proposed rule, the administration assumes that perchlorate contamination of 15 ppb is safe. But its regulatory document states that "between 16,000 and 28,000 pregnant women" and 900,000 to 2 million Americans could be exposed to higher levels. The EPA document also finds that bottle-fed infants would be exposed to more than five times the level the National Academy of Sciences deemed safe -- 700 nanograms per kilogram of body weight per day -- if parents mix formula with drinking water containing perchlorate levels of 15 ppb.

Response: Please see the response to comment code 6110. EPA has reversed its October 2008 preliminary determination not to develop an NPDWR for perchlorate and now concludes, based on the analysis presented in this notice, that there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern. Finally, EPA has determined that regulation of perchlorate presents a meaningful opportunity to reduce health risk for persons served by public water systems. EPA is initiating the development of a proposed NPDWR for perchlorate.

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120. EPA will seek comment on any specific regulatory requirements as part of a proposed national primary drinking water regulation.

Commenter Name: Ed Thomas
Commenter Organization: National Rural Water Association (NRWA)
EPA Document ID: EPA-HQ-OW-2007-0068-0163
EPA Comment ID: 20273
EPA Comment Code: 6130

Comment: Finally, NRWA feels that the issues raised by the aforementioned papers are of sufficient importance that it would be premature for the Agency to proceed with any of the possible scenarios for arriving at a perchlorate determination until these issues are resolved. For example, it is pointed out in the discussion of the evaluation of occurrence data and populations exposed (Table 5, page 24047) that this evaluation is very sensitive to the choice of an RSC and presumably to the occurrence data also. If the existing levels of contaminants are not known to any better accuracy than plus or minus a factor of 2 or more as is suggested by reference 1 above, it would not be good science to proceed with an analysis that is known to be sensitive to the value of such numbers.

Further we would encourage the agency to continue using and collecting data to support a "meaningful opportunity for public health protection" when determining if there is a clear benefit of regulating perchlorate. It is NRWA's belief that there is a need for more data to support this determination. There remain many uncertainties about the relative source contribution and the levels of perchlorate in urinary excretions. We believe that these issues along with the issues of affordability and compliance data variability must be appropriately addressed prior to the EPA Administrator making a determination regarding perchlorate, in accordance with Section 1412(b)(1)(A) of the 1996 SDWA Amendments, that "in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems."

We thank you for the opportunity to provide comments regarding this important matter.

Sincerely, Ed Thomas Ed Thomas

Electronic Attachments: 1. Phillips compliance data variability final.pdf 2. Rubin trade off health risk final.pdf

Response: EPA has made its determination based upon a consideration of the best available peer reviewed science and data collected in accordance with accepted methods related to perchlorate occurrence in drinking water, the presence of perchlorate in foods, and the health effects of exposure to perchlorate. Regarding the comment encouraging EPA to collect additional data to support the determination and to consider the papers the commenter provided, EPA believes there are sufficient data on which to evaluate the best available data to make the determination. EPA does not believe that affordability analysis is needed to make a regulatory determination. SDWA requires that EPA evaluate affordability for small systems and request comment at the time of proposing a national primary drinking water standard.

Commenter Name: Diane VanDe Hei
Commenter Organization: AMWA
EPA Document ID: EPA-HQ-OW-2008-0692-1525
EPA Comment ID: 20444
EPA Comment Code: 6130

Comment: National Academy of Sciences Review

In 2003, EPA asked the National Research Council (NRC) of the NAS to: * Assess the current state of the science regarding potential adverse effects of disruption of thyroid function by perchlorate and * Determine whether EPA's findings in its 2002 draft risk assessment were appropriate.

AMWA believes that regardless of the outcome of the final determination on perchlorate, the agency should commit to placing a similar question before the NAS for an answer by 2011.

If EPA's final decision is to regulate perchlorate, then the review of the science available since the 2005 NAS report should provide a good foundation on which to build a regulation. If the decision is not to regulate perchlorate for the present, then the review will either confirm the decision with respect to changes in the state of scientific knowledge or possibly point to the need to reassess the HRL and the regulatory determination.

Retention on the CCL

AMWA recommends that perchlorate be retained on the CCL or that some similar but less formal administrative action be taken so that changes in the science speaking to potential health effects and changes in occurrence continue to be captured and evaluated. AMWA recommends that in the final determination, EPA elaborate on how systems such as IRIS are used to keep risk and other pertinent contaminant information current and how it might be used to advantage in tracking any changes in perchlorate status.

Response: The Agency believes that a second review by the NAS would unnecessarily delay regulatory decision making for perchlorate. Therefore, EPA did not request additional NRC review of issues related to perchlorate. EPA has assessed recent best available data and has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems and has decided to regulate perchlorate in drinking water. See response to comment code 6120.

Regarding your recommendation that EPA ensure that changes in science related to potential health effects and changes in occurrence continue to be captured and evaluated, and elaborate on how systems such as IRIS are used to keep risk and other pertinent contaminant information current in tracking any changes in perchlorate status, because EPA has decided to regulate perchlorate in drinking water. EPA has found that perchlorate may have an adverse effect on human health. EPA has reversed its October 2008 preliminary determination not to develop an NPDWR for perchlorate and now concludes, based on the analysis presented in the final regulatory determination notice, that there is a substantial likelihood that perchlorate will occur in public water systems with a frequency and at levels of public health concern. Finally, EPA has determined that regulation of perchlorate presents a meaningful opportunity to reduce health risk for persons served by public water systems. The Safe Drinking Water Act requires EPA to review each National Primary Drinking Water Regulation (NPDWR) at least once every six years and revise them, if appropriate. The purpose of the review, called the Six-Year Review, is to identify those NPDWRs for which current health effects assessments, changes in technology, and/or other factors provide a health or technical basis to support a regulatory revision that will maintain or strengthen public health protection. EPA will address changes in the science and occurrence at that time.

EPA Comment ID: 20561
EPA Comment Code: 6130

Comment: I urge the U.S. Environmental Protection Agency to reverse its preliminary determination on setting a regulation for perchlorate in drinking water. It is my understanding that the effects of levels of perchlorate in our drinking water have not been fully researched. Until said testing has been performed, I believe it is inconclusive to set a standardized acceptable level of perchlorate in our drinking water. Most of all because perchlorate affects the thyroid gland almost exclusively. This fact targets our children and unborn children as their thyroids are responsible for their growth and development not just metabolism as in adults. Thank you for your time and strongly consider my plea. Sincerely, Laurence Scudder

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120.

Comment Clerk Docket EPA-HQ-OW-2008-0692 Water Docket Environmental Protection Agency Mail Code: 2822T 1200 Pennsylvania Ave., NW. Washington, DC 20460

Dear Sir:

In response to the notice in the Federal Register of October 10, 2008 (Volume 73, Number 198) the Association of State Drinking Water Administrators (ASDWA) is offering comments to the U.S. Environmental Protection Agency (EPA) on the Preliminary Regulatory Determination on Perchlorate. ASDWA is the professional Association that represents the collective interests of the nation's state drinking water programs responsible for implementation of the Federal Safe Drinking Water Act.

EPA's regulatory development activities are very important to states. Although some states have the expertise and resources to conduct their own evaluations of contaminant risks and may set their own, more stringent regulatory controls, most states rely on the EPA to determine which contaminants should be regulated in drinking water and at what levels. It is critical that these determinations are based on sound science and accomplished through a transparent process with appropriate input from all interested parties, especially states. This is especially true in the case of perchlorate, since this contaminant has garnered extensive public and political interest in the last few years.

ASDWA appreciates the opportunity to provide the perspective of states on the Agency's preliminary determination for perchlorate. States are generally in favor of EPA's decision not to regulate, but there are some states that do favor national regulation of perchlorate, especially those who have already set their own standard. The Agency should expect direct comments from some of these states. We do have a few recommendations to offer related to the perchlorate decision about tools and information that we believe would benefit to all states. These recommendations do not include a recommendation to regulate, but they do go beyond the norm.

Regardless of EPA's regulatory decision, states will need to act - Even if EPA does not adopt a national regulation of perchlorate, the public will likely demand a response to detections of elevated levels of perchlorate - particularly, in light of the notoriety associated with this contaminant. The occurrence data may not support regulation of perchlorate, but the data do show that there are a significant number of water sources where perchlorate was detected, and at least a few where the levels are a public health concern. Because the decision not to regulate was based on a low national number of detects at levels of concern and not a lack of health effects, there is still a need for action in some cases, even if a national standard is not justified. In states where there are detections of perchlorate at levels of concern, drinking water programs need to be able to respond appropriately so that public health can be protected. At a minimum, states will need to assist individual water systems with the specific actions needed to control perchlorate. Information is needed from EPA on risk characterization and risk management as well as treatment options and alternative control measures to support state efforts. In some cases, a state may decide that perchlorate is common enough in their source waters that they are interested in developing statewide control measures, whether it is a formal monitoring program or a state specific MCL. We believe the Agency has data and expertise that can help support these actions.

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120. EPA will provide further risk characterization and risk management information as part of the national primary drinking water standard.

Commenter Name: Lewis Zediana
Commenter Organization: Tewksbury Water Department
EPA Document ID: EPA-HQ-OW-2008-0692-1670
EPA Comment ID: 20669
EPA Comment Code: 6130

Comment: Please find attached my comments on this subject.

Perchlorate should not be dropped from the list. Montioring can be adjusted by allowing waivers while taking into consideration the surrounding area and chances of contamination. However more protection can be afforded to the populace by expanding the monitoring program to the effluent of wastewater plants. Which as by our experience can release Perchlorate passed inot the system..

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120. EPA intends to present specific regulatory requirements for public water systems (including monitoring) for public comment with the proposed NPDWR. This action does not address waste water discharges.

Commenter Name: Lyndsey Crum
Commenter Organization:
EPA Document ID: EPA-HQ-OW-2008-0692-1732
EPA Comment ID: 20679
EPA Comment Code: 6130

Comment: While I support the EPA's desire to not promulgate NPDWR for perchlorate for the reason above, I am concerned about the health implications this will have for the sensitive subpopulations of infants, pregnant women and those likely to become pregnant. Although the

connection between perchlorate and thyroid related health and cognitive defects is not conclusion, the EPA presents evidence that suggest such a link could exists. The possibility should be sufficient to warrant clearer, quantitative research targeting these populations, particularly in industrial communities where perchlorate could enter the public water supply.

In addition to a targeted study, the agency should consider the costs of not regulated perchlorate versus the possible treatment costs associated with thyroid conditions. Regulatory cost saving should not outweigh the cost of prevention.

Although the EPA is not required to promulgate NPDWR for perchlorate, should it conduct additional research, in which that research produces a strong health risk concern; EPA should create a NPDWR to address regulation needs. The regulation could be enforcing only when the state health agency has not already passed a sufficient state public drinking water regulation.

Lyndsey Crum lcrum10@law.du.edu

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120. To do so, EPA used the best available peer-reviewed science and does not think that an additional targeted study is necessary at this point. EPA intends to develop a proposed NPDWR, at which time EPA will analyze, among other things, quantifiable and nonquantifiable health risk reduction benefits as well as costs of a rule, the effects of perchlorate on the general population and specific life stages, and other relevant factors with respect to the degree and nature of the risk. See 42 USC 1412(b)(3)(C).
Because EPA has decided to regulate perchlorate in drinking water the Safe Drinking Water Act requires EPA to review each National Primary Drinking Water Regulation (NPDWR) at least once every six years and revise them, if appropriate. The purpose of the review, called the Six-Year Review, is to identify those NPDWRs for which current health effects assessments, changes in technology, and/or other factors provide a health or technical basis to support a regulatory revision that will maintain or strengthen public health protection. EPA will evaluate changes in the science and occurrence at that time.

EPA Document ID: EPA-HQ-OW-2008-0692-1770
EPA Comment ID: 20927
EPA Comment Code: 6130

Comment: Without an enforceable federal standard, the Department of Defense, which is a primary user of perchlorate in the U.S., will perform remediation efforts according to a patchwork of state and agency guidelines. According to the EPA, approximately 90 percent of perchlorate produced in the United States is for defense activities and NASA.[FN7: EPA (2007). Perchlorate. Environmental Protection Agency, Federal Facilities Restoration and Reuse. Retrieved Oct. 24, 2008 from http://www.epa.gov/fedfac/documents/perchlorate.htm.] Recognizing perchlorate contamination is a defense-related hazardous waste issue with significant potential impact on human health, the Department of Defense (DOD) designated perchlorate as an emerging contaminant and has taken some action to clean up contamination, mostly in the form of responding to requests made by the EPA and states-requests that relied on piecing together statutes, regulations, and the

power of oversight agencies.[FN8: GAO (2007). Department of Defense Activities Related to Trichloroethylene, Perchlorate, and Other Emerging Contaminants. Government Accountability Office. July, 2007. Retrieved October 24, 2008 from http://www.gao.gov/new.items/d071042t.pdf.] While the DOD is responsible by law for remediation of contaminants regulated by the EPA or the state, its responsibility for what it classifies as "emerging contaminants" is not clearly defined.

In 2006, the DOD adopted its own management policy in which they are to comply with state or federal standards, whichever is most stringent. According to this policy, in the absence of state or federal standards, the DOD will manage its control action using 24 parts per billion (ppb) as the level of concern. Because a federal standard has not yet been established, the DOD must use state regulations to guide its remediation efforts. But while a handful of states have nonregulatory perchlorate-level guidelines, only two states-Massachusetts and California-have set enforceable perchlorate drinking- water standards (1 ppb and 6 ppb respectively). Perchlorate contamination and its potential adverse health impacts, however, is obviously a multistate issue.[FN9: GAO 2007 finds federal and state agencies have found perchlorate in groundwater, surface water, soil, or public drinking water systems at almost 400 sites representing over 37 states, in concentrations that ranged from 4 parts per billion (ppb) to more than 3.7 million ppb. http://www.gao.gov/new.items/d07797t.pdf] Without a federal standard, not only will the DOD have to overcome the difficult challenge of performing remediation efforts according to varied guidelines, but states that currently lack their own enforceable standards and have known sources of perchlorate may be left with remediation efforts based on the DOD's 24 ppb management standard.

In the absence of a federal standard, remediation efforts by EPA and state officials of public drinking water systems contaminated by perchlorate have been shown to be nonexistent. DOD remediation efforts are not alone in their need for guidance from a federal perchlorate standard-cleanup of perchlorate in public drinking water systems has been shown to be nonexistent without a federal standard. According to research done by the GAO, "EPA and state officials told us they had not cleaned up contaminated public drinking water systems, principally because there was no federal drinking water standard or specific federal requirement to clean up perchlorate."[FN10: GAO. (2007). Perchlorate: EPA Does Not Systematically Track Incidents of Contamination. Retrieved Oct 27, 2008 from http://www.gao.gov/new.items/d07797t.pdf.]

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120.

Comment: DETAILED COMMENTS

1. EPA has made a preliminary determination not to set a health standard for perchlorate without reviewing or considering peer review and public comments on key pieces of evidence which it relies upon for its determination.

As EPA announced in its preliminary determination on perchlorate, the Agency is planning to issue a final determination by December 2008. However, NRDC has learned that the PBPK peer review reports of the staff report have only recently been submitted to EPA and were not incorporated into EPA's analysis in making its regulatory determination. Furthermore, NRDC has learned that EPA has solicited peer review comments on the HRL itself, and to date, is still awaiting those comments. EPA should not proceed with any decision on perchlorate until all the peer review reports have been submitted to EPA, reviewed by EPA scientific staff and managers, and made available for public scrutiny.

If EPA finalizes its preliminary determination, in the absence of strong state drinking water standards for perchlorate, the HRL will provide the only guidance for Superfund cleanup levels and health advisories for perchlorate. The importance of the HRL if EPA chooses not to regulate perchlorate underscores the importance that it be fully peer reviewed and those comments be made available to the public before EPA finalizes its determination. There is no justification for EPA's apparent intent to race ahead with a decision not to set a health- standard for perchlorate, and to rely upon an inadequate health reference level, prior to receiving, considering, and responding to both peer review and public comment. Failing to give these comments sufficient consideration in making its final determination would render EPA's final action arbitrary and capricious.

Response: All the peer review reports have been submitted to EPA, reviewed by EPA, and made available for public scrutiny. EPA has considered the results of the peer review reports in reaching the determination it announces today to regulate perchlorate in drinking water. See response to comment code 6120.

Water Docket, EPA Mailcode 2822T 1200 Pennsylvania Ave. Washington, DC 20460

Re: EPA-HQ-OW-2008-0692

I am writing to express my concerns regarding the issue of perchlorate levels in our drinking water in the United States. I feel this chemical should be further studied and monitored in our drinking water and water tables, and eliminated as much as possible. For the future of our children and their children, please continue to study the effects of perchlorate do not allow this chemical to remain uncontrolled in our drinking water.

Thank you, Dawn M. Lee

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120. To do so, EPA used the best available peer-reviewed science. EPA intends to present specific regulatory requirements for public water systems (including monitoring) for public comment with the proposed NPDWR.

Environmental Protection Agency Water Docket 1200 Pennsylvania Ave. Washington, DC

RE: EPA-HQ-OW-2008-0692

Dear Sirs/Madam:

A recent online review of information about perchlorate proved very interesting. It seems that several states are imposing limitations on the presence of perchlorate in water; however the recommended "safe" levels are inconsistent.

I feel that in order for the public to be protected by the potential risks associated with ingesting perchlorate, the EPA should conduct further, in depth studies into the actual ramifications of this chemical.

Instituting a drinking water regulation cannot be done until accurate, authoritative research into the health impacts is conducted.

I look forward to seeing the results of such tests in a timely manner.

Carrie Manion Resident of Anne Arundel County, Maryland

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120. To do so, EPA used the best available peer-reviewed science. EPA intends to conduct further analyses, pursuant to the requirements of 42 USC 300g-1(3)(C)(i), in promulgating the NPDWR with a maximum contaminant level.

Comment: All Americans deserve healthy and clean drinking water. The EPA should not finalize this decision until the scientific review is complete and should make decisions that are consistent with the agency's own scientists. Contrary to your claims, protecting the health of young children is indeed a "meaningful opportunity for health risk reduction."

Response: All the peer review reports have been submitted to EPA, reviewed by EPA, and made available for public scrutiny. EPA has considered the results of the peer review reports in reaching the determination it announces today to regulate perchlorate in drinking water. See response to comment code 6120.

Comment: Water Docket Environmental Protection Agency Mailcode 2822T,1200 Pennsylvania Avenue Washington, DC 20460

ATTN: Docket ID No. EPA-HQ-OW-2008-0692

To whom it may concern:

Perchlorate contamination in drinking water is a nationwide problem. As noted recently by the EPA's own Scientific Advisory Board, perchlorate's widespread occurrence in drinking water and its well-documented toxicity to humans make it vital to have the best scientific evidence available in making a determination as to whether or not perchlorate levels should be regulated. Given its potential for posing significant risks to human health, I urge the EPA to delay final action on its decision not to set a federal drinking-water standard for perchlorate. I support a national primary drinking water regulation governing perchlorate levels to protect public health.

Yours sincerely, Susanna Sayre 19005 Bloomfield Rd. Olney, MD 20832

Response: EPA has determined to regulate perchlorate in drinking water. See response to comment code 6120.

September 24, 2009 Comment Clerk Docket EPA-HQ-OW-2009-0297 Water Docket Environmental Protection Agency Mail Code: 2822T 1200 Pennsylvania Ave., NW. Washington, DC 20460

Dear Sir:

In response to the notice in the Federal Register of August 19, 2009 (Volume 74, Number 159) the Association of State Drinking Water Administrators (ASDWA) is offering comments to the U.S. Environmental Protection Agency (EPA) on the Perchlorate Supplemental Request for Comments. ASDWA is the professional Association that represents the collective interests of the nation's state drinking water programs responsible for implementation of the Federal Safe Drinking Water Act.

EPA's regulatory development activities are very important to states. Although some states have the expertise and resources to conduct their own evaluations of contaminant risks and may set their own, more stringent regulatory controls, most states rely on the EPA to determine which contaminants should be regulated in drinking water and at what levels. It is critical that these determinations be based on sound science and accomplished through a transparent process with appropriate input from all interested parties, especially states. This is particularly true in the case of perchlorate, since this contaminant has garnered extensive public and political interest in the past few years. We appreciate that EPA is sharing its assessment of health risk and occurrence data and requesting additional comment as important regulatory decisions are considered.

As we noted in our comments on EPA's preliminary decision on perchlorate regulation in October 2008, states were generally in favor of EPA's preliminary decision not to regulate, but there are some states that do favor national regulation of perchlorate, especially those who have already set their own standard. In that response, we did recommend some tools and information that we believed would benefit all states. Our comments today will address some of the questions in the Agency's August 19th request for comments, but also reiterate some of the recommendations in our previous letter, where appropriate.

Response: Please see the response to comment code 6110.

EPA Document ID: EPA-HQ-OW-2009-0297-0638
EPA Comment ID: 28748
EPA Comment Code: 6130

Comment: In summary, the NDEP believes the EPA should develop a national primary drinking water standard for perchlorate using updated, appropriate, and complete data sets; defensible analysis; and scientific approaches. The States and general public place a tremendous amount of trust in the EPA to make credible decisions. Consequently, we trust the EPA will thoughtfully consider our comments and those submitted by other entities during its current evaluation. Much more significant public health benefit is achievable and at a much lower cost by targeting iodine-deficient individuals through existing public health programs and correcting the iodine deficiencies through adjusted diets, use of supplements, and implementation of educational programs. These concepts are not new, yet they have not been addressed in a meaningful way. Congress is capable of funding such programs and should be requested to do so in the near term.

Sincerely, Tom Porta, Deputy Administrator Nevada Division of Environmental Protection

Comment: Dear Sir,

We have developed a new method for detection of perchlorate in aqueous solution with remarkably high selectivity. The method is likely to be low- cost relative to exisiting approaches (e.g., those described at http://www.clu-in.org/contaminantfocus/default.focus/sec/perchlorate/cat/Overview/) and suitable for field work. We are preparing a manuscript for submission to the Journal of the American Chemical Society describing the discovery. I expect the document will be submitted within 10 days.

The science described in that account is covered by a provisional patent. We have recently made some significant improvements which will greatly increase the sensitivity. If this sounds relevant, please feel free to contact me.

Professor Bill Connick University of Cincinnati (513)-556-0148 bill.connick@uc.edu

Regards, Bill

Response: EPA cannot evaluate methods that have not been peer reviewed. However, EPA will evaluate the best available, peer reviewed literature as the NPDWR is developed.

Water Docket Environmental Protection Agency Mailcode: 2822T 1200 Pennsylvania Avenue Washington, DC 20460

RE: Perchlorate Supplemental Request for Comments (Docket ID No. EPA-HQ- OW-2009-0297)

Dear Sir/Madam:

The New Jersey Farm Bureau (NJFB) is a 13,000 member organization which represents New Jersey agricultural producers and enterprises at all levels of government. We thank the Environmental Protection Agency (EPA) for the opportunity to provide comments on the above referenced docket regarding alternative approaches to the interpretation of scientific data relevant to establishment of a national primary drinking water regulation for perchlorate.

We believe that the approaches EPA described in the August 19, 2009 Federal Register deviate from long-established methods by which EPA has analyzed scientific and technical data. We are concerned that development of an overly conservative standard for perchlorate, that is not based on comprehensive, peer- reviewed science and an appropriate risk-based assessment could unintentionally lead to unjustified food scares associated with a wide variety of agricultural commodities. Food scares of this nature could deter people away from consuming foods which the Food and Drug Administration (FDA) encourages people to eat more of due to their nutritional benefits and which the FDA has deemed critical to the health and development of children. Furthermore, we are concerned about the economic impacts associated with such food scares.

Response: SDWA requires the consideration of sensitive subpopulations in developing NPDWRs. EPA exposure assessment policy has evolved to provide tools and policies consistent with the concern for all life stages. See responses to comments IDs 28813 and 28677 under comment code 6140.

Commenter Name: Stephen Haterius
Commenter Organization: National Association of State Departments of Agriculture (NASDA)
EPA Document ID: EPA-HQ-OW-2009-0297-0664
EPA Comment ID: 28548
EPA Comment Code: 6140

Comment: We remain very concerned that the approaches EPA outlined in the August 19 Federal Register will significantly-and unnecessarily-impact American agricultural production and foreign trade. Because perchlorate is naturally occurring at low levels in a number of agricultural products, it is imperative that EPA's regulatory determination be based upon a sound scientific approach that protects public health without unnecessarily creating concerns about the safety of agricultural products that are vital to a healthy diet. This is particularly important in light of the fact that the risks associated with perchlorate can be easily avoided by the consumption of sufficient iodine-rich foods or iodine supplements by a specific subset of the population.

As we detailed in previous comments, an overly conservative perchlorate standard that is not based on sound, peer-reviewed science and an appropriate risk-based assessment could unintentionally lead to unjustified food scares on a wide variety of fresh fruits, vegetables, and dairy products. Even though EPA's current action is intended only to explore alternative approaches to analyzing data, the additional alternatives under consideration could result in health reference levels which are much lower than the level identified in the October 2008 notice. NASDA is concerned that this kind of standard would likely lead to inaccurate consumer perceptions and confusion about perchlorate in agricultural products. The ramifications of this kind of food scare would have devastating impacts on agricultural producers and rural communities. For example, a study by Arizona State University indicates that a prolonged food scare involving winter lettuce could result in a negative economic impact of over $5 billion.

Moreover, EPA's actions could have significant impacts on American producers' access to foreign markets. The agricultural products impacted by this issue represent nearly $70 billion in export opportunities. Because other countries frequently cite food safety concerns as justifications to erecting trade barriers to American agricultural products, an overly conservative perchlorate standard that is not based on sound, peer-reviewed science and an appropriate riskbased assessment would likely lead to the imposition of unfair and economically devastating trade restrictions by America's trading partners.

Response: See responses to comments IDs 28813 and 28677 under comment code 6140.

Commenter Name: Anonymous
Commenter Organization:
EPA Document ID: EPA-HQ-OW-2009-0297-0653
EPA Comment ID: 28559
EPA Comment Code: 6140

Comment: Further conservatism (i.e. more stringent assumptions) concerning hazard or exposure beyond central tendencies in the existing data sets is not justified. To follow a precautionary principal in setting further restrictions in this case is both arbitrary and capricious. Further, without a clear basis for protecting public health, the Agency will cause public and private water providers to expend energy to remove perchlorate from water supplies that already protect their consumers. The Agency has failed to estimate the carbon emissions and cost that this unnecessary removal, probably through dedicated reverse osmosis systems, will cost the American public in higher water rates and carbon emissions. The Agency has provided no data on the feasibility of removing perchlorate below the preliminary guidance level. In doing so, costs must be estimated for both the construction capital costs and based on energy expenditures which are an ongoing annual cost rather than a one-time capital cost. Such ongoing costs must be considered for the life of the project.

Response: See response to comment ID 28813 under comment code 6140.

Commenter Name: Sonia Salas
Commenter Organization: Western Growers Association on behalf of several California agriculture groups
EPA Document ID: EPA-HQ-OW-2009-0297-0652
EPA Comment ID: 28677
EPA Comment Code: 6140

Comment: We are further concerned that the food scares which will follow from setting a regulatory threshold below the existing natural background level of perchlorate in the environment will significantly disadvantage agricultural exports. Agricultural commodities make up a significant portion of all U.S. food exports. Given the long history of our Asian trading partners taking retaliatory actions for what they deem to be U.S. protectionism -- we are particularly concerned in light of the Obama Administration's recent announcement to impose tariffs on Chinese tire manufacturers -- a regulatory determination which does not take into consideration the presence of naturally occurring perchlorate will provide an unfortunate opportunity for the Chinese government to make good on their threats to punish U.S. agricultural exports.

Response: EPA is aware of the need to communicate clearly the implications of the NPDWR that is developed. The NPDWR as currently envisioned assumes that no change will be required to the food supply. Adjustment to perchlorate exposure will be made in the drinking water supply, assuming that the food supply remains in its current state with regard to perchlorate.

Comment: Please see the attached comment letter regarding the perchlorate supplemental request for comments. Thank you.

Robert Callahan California Chamber of Commerce

October 8, 2009

Ms. Lisa P. Jackson Administrator Environmental Protection Agency 1200 Pennsylvania Avenue, NW Washington, DC 20460

SUBJECT: EPA-HQ-OW-2009-0297, "Drinking Water: Perchlorate - Supplemental Request for Comments"

Dear Ms. Jackson:

The California Chamber of Commerce (CalChamber) wishes to express our concern with the federal Environmental Protection Agency's (EPA) interpretation of the scientific data relevant to a regulatory determination for perchlorate in drinking water. While it is imperative to set public health standards, especially where a specific threat exists, there is no rationale for establishing lower standards or for rushing to a regulatory decision unsupported by scientific information.

Perchlorate is found naturally throughout the water environment in the 0.5 to 15 parts per billion range. The United States Geological Survey and other researchers have also measured perchlorate in rain, geologic formations, and rivers and aquifers throughout the United States. Five decades of scientific investigation, including a landmark National Academy of Sciences review, result in a clear and consistent conclusion: low levels of perchlorate are not dangerous to public health.

We strongly believe that an unnecessarily lower standard would limit the flexibility of the water supply system. Curbs on water supplies, especially during a water emergency, would impact local economies and job markets, as plans for new housing areas and business centers are postponed or cancelled due to lack of available water. Current residential areas and businesses could also be forced to endure unnecessary water shortages, water rationing, rate hikes and other consequences.

In light of this, it seems clear that the alternatives proposed by EPA are not justifiable considering the significant economic costs that would be incurred without corresponding benefits to public health. Please keep these considerations in mind as the EPA determines additional approaches to interpreting perchlorate level data.

Sincerely, Robert Callahan Policy Advocate RC:fg

Response: See response to comment ID 28813 under comment code 6140. As explained elsewhere in this response to comments document (comment ID 28863 under comment code 2110), EPA believes that the RfD derived by the NRC is the best health assessment available for assessing risk to perchlorate.

Comment: Appendix 1

A first step towards a possible link perchlorate-organohalogens-TH

It has been shown that chlorine-based disinfectants such as those found in drinking water oxidize to perchlorate as a disinfection by-product (DBP). This is, for example, why Massachusetts doubled its MCL from 1 to 2 ppb, because otherwise health-protecting chlorination of drinking water and swimming pools with bleach would have to be curtailed. Is this oxidation of perchlorate from bleach (hypochlorite and hypochlorous acid) and other chlorine derivates significant in comparison with daily intake of perchlorate?

According to the Blount study (based on the NHANES survey data) the average urinary perchlorate level in the population is 2.84ug/l which is roughly equivalent to an oral dose of 0.04 ug/kg-day. This corresponds with drinking water of 1.4 ppb. Massachusetts' MCL was based on data that showed that about 0.5 ppb perchlorate originated from bleach alone[FN16: -Massachusetts Department of Environmental Protection. Perchlorate: Draft Toxicological Profile and Health Assessment. 2004. - Occurrence of Perchlorate in Sodium Hypochlorite, Journal American Water Works Association (AWWA), Nov. 2008.]. Therefore about 1/3 of the average daily intake of perchlorate would be due to bleach oxidation alone, which is substantial and which shows that chlorine could be a significant source of low level perchlorate.

Bleach is used ubiquitously, as for example in water purification stations, paper mills, drinking water and for many other applications. Other potential sources of perchlorate as a DBP are other chlorine derivates such as chlorine gas and chloramine. On the other hand other DBPs originate from the reaction of chlorine based disinfectants with organic matter (waste) to form organochlorides[FN17: Gary A. Boorman, Vicki Dellarco, June K. Dunnick, Robert E. Chapin, Sid Hunter, Fred Hauchman, Hank Gardner, Mike Cox, and Robert C. Sills. Drinking Water Disinfection Byproducts: Review and Approach to Toxicity Evaluation. Environmental Health Perspectives Supplements, February 199, Volume 107, Number S1.]. What could be one of the possible pathways that link perchlorate to organochlorides such as PCBs via chlorine?

According to EPA the building block for organochlorides is chlorophenol, and chlorophenols are produced from the organic matter found in used water when it reacts with chlorinated disinfectants[FN18: Environmental Protection Agency, EPA/600/P-03/002F).An Inventory of

Sources and Environmental Releases of Dioxin- Like Compounds in the United States for the Years 1987, 1995 and 2000. Federal Register: December 1, 2006 (Volume 71, Number 231)] Page 69564-69565] Occurrence of Perchlorate in Sodium Hypochlorite, Journal American Water Works Association(AWWA), Nov. 2008] (phenol is benzene with a hydroxyl group and PCBs are basically 2 chlorinated benzene rings). Those DBPs are found back in the drinking water leaving the water purification plants.

Therefore, this is one example of the possible link between very low levels of perchlorate and TH affecting substances: chlorine based disinfectants such as bleach, Cl2 and chloramines evolve to perchlorate in one way and to phenols, PCBS and other organochlorides including dioxin-like compounds in another way. [Chloramines, besides being an added disinfectant, can also be formed as a reaction product of bleach with ammonia, itself amply present in used water (see ref. 15)].

Response: EPA is aware of the link between perchlorate and hypochlorite/hypochlorous acid. This issue, and those related to other possible transformation products, will be considered in the context of NPDWR development.

EPA Comment ID: 28813
EPA Comment Code: 6140

Comment: A Final MCL Below 1 ppb is Both Technologically and Economically Feasible

U.S. EPA's Method 314 approved ion chromatography detection protocol, for example, routinely detects perchlorate pollution at levels of 0.2ppb and the State of Massachusetts has established a 'reportable concentrations level for perchlorate of 2 ppb.[FN66: Thorne, Philip G. Field Screening Method for Perchlorate in Water and Soil, ERDC/CRREL Technical Report 04-8, 36 pp, Apr 2004.],[FN67: "Final Changes to the Massachusetts Contingency Plan -310 CMR 40.0000," downloaded from http://www.mass.gov/dep/cleanup/laws/perchlorate-310CMR40-07282006.pdf, November 2 2006.] Ion exchange technology is able to treat perchlorate contamination to levels considerably below 1 ppb. Treatment systems operating on perchlorate- impacted wells owned by Aquarion Water Company in Massachusetts, for example, treat wells to below 1 ppb.[FN68: "US Filter Recovery Services," downloaded from www.usfilter.com, November 2 2006.]

Economically, the cost of complying with a perchlorate MCL less than 1 ppb for the City of Rialto - one of the most impacted water systems in California - for example will be zero after cleanup costs are recovered from identified responsible parties. A complete economic feasibility study should also include an analysis of the costs associated with healthcare and lost work resulting from illnesses associated with perchlorate contaminated water.

Response: EPA agrees that analytical methods and treatment techniques are available to address increasingly smaller concentrations of perchlorate. As the NPDWR is developed, economic feasibility will be evaluated in support of identifying an MCL.

Additional NDEP Comments to "Drinking Water: Perchlorate Supplemental Request for Comments" noticed by the USEPA in the August 19, 2009 Federal Register.

These additional comments focus on: (1) the lack of a demonstrative environmental or public health benefit being realized when an MCL is applied to existing well-managed remediation sysytems in the Las Vegas Valley if a low standard is developed that does not consider all of the recent epidemiological literature; and (2) analytical challanges associated with accurately measuring perchlorate in water with elevated EC.

October 8, 2009

U.S. Environmental Protection Agency Mailcode 2822T 1200 Pennsylvania Ave., NW. Washington, DC 20460

Subject: Docket ID No. EPA-HQ-OW-0297

Reference: Drinking Water: Perchlorate Supplemental Request for Comments (Federal Register / Vol. 74, No. 159 / Wednesday, August 19, 2009 / Notices

The Nevada Division of Environmental Protection (NDEP) submits these additional comments in response to the referenced "Supplemental Request for Comments" noticed by the U.S. Environmental Protection Agency (EPA) in the August 19, 2009 Federal Register; Docket ID No. EPA-HQ-OW-2009-0297. These comments are submitted in addition to comments previously provided by the NDEP dated September 16, 2009. The comments are provided within the extended comment period and are designed to assist the EPA in their efforts in evaluating whether there is a meaningful opportunity for human health risk reduction of perchlorate to persons served by public water systems through promulgating a national primary drinking water rule for perchlorate.

The NDEP understands that in order to regulate a contaminant in drinking water [i.e., develop a maximum contaminant level (MCL)], EPA must determine that the contaminant meets the following three criteria:

1) The contaminant may have an adverse effect on human health;

2) The contaminant is known to occur (or there is a substantial likelihood that the contaminant will occur) in public water systems, with a frequency and at levels of public health concern; and

3) Regulation of such a contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems.

These additional comments focus on two primary elements:

* The lack of a demonstrative environmental or public health benefit being realized when a drinking water standard (maximum contaminant level [MCL]) is applied to permitted waste water discharges from existing well-managed remediation systems in the Las Vegas Valley if a low standard is developed that does not consider all of the recent epidemiological literature; and

* analytical challenges associated with accurately measuring perchlorate in water with elevated electrical conductivity (EC).

Lack of Benefit Realized and Difficulties Applying a Very low MCL:

MCLs are used by States, Territory's, and the Federal government to determine when an action may be required (action level) as well as when remediation may cease (remediation standard). Additionally, many regulatory agencies (including the NDEP) use MCLs, when they are available, for water quality criteria applicable to water quality permits. Two principal permit programs overseen by the NDEP in the State of Nevada are the National Primary Discharge Elimination System (NPDES) program and the Underground Injection Control (UIC) program. Permits issued by these programs not only are used to regulate the water quality of waste water discharges from various industries and governmental entities; these permits are also used to regulate the water quality of discharges from environmental remediation systems. Use of MCLs to set discharge limitations in these permitting programs where drinking water is the designated beneficial use of the receiving water is typical throughout the US.

Two significant environmental remediation projects are actively remediating perchlorate-impacted groundwater within the Las Vegas Valley (NDEP 2009). Tronox (formerly Kerr-McGee) operates a Fluidized Bed Reactor (FBR) that treats approximately 1,000 gallons per minute (gpm) with a typical influent concentration of approximately 500 milligrams per liter (mg/L) perchlorate. AMPAC operates an In-situ Bioremediation (ISB) system that treats approximately 200 to 300 gallons per minute with a typical influent concentration of 20 to 30 mg/L perchlorate. Both treatment systems additionally treat (destroy) large amounts of chlorate and nitrate due to the advantageous use of bioremediation. Bioremediation of perchlorate is nonselective; hence significant environmental and human health benefits are realized through use of these technologies (FBR and ISB) to treat large volumes of water impacted with elevated concentrations of perchlorate.

Both the Tronox and AMPAC bioremediation systems are designed to operate with more electron donor provided than is necessary to destroy all of the nitrate, chlorate, and perchlorate present within the influent water. These treatment systems are designed this way because it would be incredibly difficult to precisely meter an amount only necessary for the required mass destruction given that small changes in influent concentrations (of perchlorate, chlorate, and nitrate) occur. As such, the treatment systems are designed and the actual operations are managed in ways that the treated water typically exhibits no detectable concentration of perchlorate. Stated another way, there is no advantage to operate these remediation systems in a manner that conserves electron donor but puts the permittee (Tronox and AMPAC) at risk of a NPDES or UIC permit violation.

The practical challenge is not one of treatment system design and operation, but rather of monitoring. Significant challenges exist in identifying and quantifying perchlorate in the Tronox NPDES permitted discharge and AMPAC UIC permitted discharge at values typically less than approximately 10 ug/L and 6 ug/L, respectively. Additionally, the actual environmental benefit that could be perceived to be present if the permit discharge values were lowered significantly is in the

range of less than 1/2 pound per day mass loading to the receiving waters. The down side associated with placing a significantly lower standard on the referenced permits is that the two treatment systems would be precariously positioned for permit exceedance. It makes little sense to the NDEP to effectively establish discharge permit conditions that increase potential for noncompliance with two very important and very successful perchlorate treatment systems and at the same time provide no measureable environmental benefit or public health risk reduction.

Analytical Challenges:

Most perchlorate remediation that occurs throughout the United States involves significantly lower concentrations of perchlorate particularly when higher amounts of water are treated. Additionally, the baseline water quality applicable to those remediation projects is much different on those projects than for projects within the and Mojave Desert region of the southwestern United States including projects within the Las Vegas Valley. Total dissolved solids (TDS) concentrations of shallow groundwater within the Las Vegas Valley typically exceed 1,000 mg/L and often can be measured between 3,000 and 10,000 mg/L. Electrical conductivity (EC) measurements (specific conductance) often are used in lieu of TDS measurements to permit rapid, cost-effective analysis of water quality when monitoring ground water, surface water, and NPDES and UIC permitted discharges. Although EC and TDS measurements are not identical, the two are well correlated.

It is important to note that the treated water discharged from the Tronox FBR remediation system typically measures in the range of 10,000 mg/L. Similarly, it is helpful to know that the donor-amended water injected via a UIC permit by AMPAC to allow for ISB of perchlorate typically measures in the range of 3,000 to 4,500 mg/L TDS. The analytical method routinely used to quantify perchlorate in water is EPA Method 314.0 or 314.1. Both of these Ion Chromatography (IC) based methods do not provide reliable results when the water samples being tested are in the range (or exceed) approximately 7,000 us/cm (reference Table 1 and the related analytical summaries in Attachment A). Additionally, these methods are presumptive methods in that they do not provide a definitive determination that the detected analyte is perchlorate as can be seen in Table 1. The influent water to the above referenced treatment systems additionally contain a number of other analytes that can co-elute or otherwise compromise the detection and quantification of perchlorate. It is for these reasons that:

* Other methods have been developed for use particularly with saline samples;

* Mass spectrometry (MS) is used as the detector in more robust analytical methods that are preferred by many knowledgeable chemists and other professionals working with perchlorate identification, quantification, and remediation as these advanced methods provide superior results; and

* It is very difficult to identify and quantitate perchlorate to very low concentrations (generally less than between 6 and 10 ug/L) in water that exhibits elevated TDS and/or other confounding analytes.

In summary, the NDEP recommends EPA conduct a thoughtful review of all of the data and literature at this time. EPA should consider the side-effects and unnecessary costs external to the Safe Drinking Water Program (SDWA) that are involved with using the proposed methodologies to set an MCL at a level that is not readily attainable nationally using available analytical methods and

readily available equipment. Alternatively, EPA should demonstrate additional measureable environmental or public health benefit that would justify these additional external costs. The selection of appropriate analytical methods for use in different applications (drinking water, waste water, treated water from remediation systems) is crucial to enable the collection of useable data. Additionally, the application, of a scientifically based defensible regulatory standard (Health Advisory, MCL, or other standard) throughout the perchlorate remediation and monitoring process is a critical component to successful remediation and monitoring of perchlorate in environmental media.

We trust the EPA will thoughtfully consider our comments and those submitted by other entities during its current evaluation.

Sincerely, Tom Porta, Deputy Administrator Nevada Division of Environmental Protection

Comment: Consideration of Studies Published since EPA adopted the NAS RfD for perchlorate

In addition to the noted epidemiological, exposure assessment, and occurrence studies, AWWA would like to direct the Agency's attention to other references that should bear on the decision making process following this comment period.

- AWWA and Water Research Foundation. 2009. Hypochlorite - An Assessment of Factors That Influence the Formation of Perchlorate and Other Contaminants.

Considering that perchlorate has been under review for Federal regulation and is currently regulated in California and Massachusetts (proposed in New Jersey), this study was commissioned to quantify potential perchlorate contributions from hypochlorite sources. Sodium hypochlorite is a commonly used form of chlorine in drinking water and water reuse applications for its ability to disinfect and maintain a residual level of disinfectant throughout the distribution system. Approximately 1/3 of all drinking water treatment plants (DWTPs) in the United States use bulk hypochlorite for disinfection. [FN21: AWWA Disinfection Committee. 2008. Committee Report: Disinfection Survey Part 2 - Alternatives, experience and future plans. Journal AWWA. 100:11.] Though the majority of liquid hypochlorite use is in the form of bulk hypochlorite delivered from regional manufacturers and/or distributors, and some use on-site hypochlorite generators (OSG).

The data set for this study was limited to 12 OSG sites, 6 bulk hypochlorite sites, and 1 calcium hypochlorite site. This sample set suggested no difference between bulk sodium hypochlorite solutions, OSG solutions, and calcium hypochlorite solutions with respect to chlorate and perchlorate ion concentration, with the exception being bromate formation. The analysis did demonstrate the potential to exceed some existing state standards and HRLs proposed by the Agency. Therefore, as more pressure is placed on utilities using gaseous chlorine to move towards alternative disinfection practices for security related reasons, the sector requires more detailed information to fully characterize potential differences (in terms of contaminant formation/dosing) between the available options to avoid unintended future water quality consequences and proper consideration of the risk- risk tradeoffs.

- Russell, C., Roberson, A., Chowdhury, Z., and M. McGuire. 2009. National Cost Implications of a Perchlorate Regulation. Journal AWWA. 101:3:54.

Recognizing a lack of available information on projected national costs associated with perchlorate treatment, a study was conducted to estimate the national cost implications of setting a federal maximum contaminant level (MCL) for perchlorate at different levels between 4 and 24 ug/L. At the most stringent potential MCL evaluated (4 ug/L), the national compliance cost was estimated to be between $76 and $140 million per year at a 3% discount rate. The relatively low national compliance cost for perchlorate reflects the small number of public water systems (PWSs) expected to be affected (3.4% at a perchlorate MCL of 4 ug/L based on 90th percentile perchlorate concentrations). However, the cost impacts to an individual system installing perchlorate treatment would likely be significant. With operations and maintenance (O&M) costs for perchlorate treatment over a 20-year period comparable to the capital costs for construction and with these O&M costs continuing in perpetuity, ratepayers could face a significant increase.

Response: As the NPDWR is developed, economic feasibility will be evaluated in support of identifying an MCL. EPA will consider the best available, peer reviewed literature on the full range of issues embodied in an NPDWR, including risk-risk tradeoffs.

EPA Document ID: EPA-HQ-OW-2009-0297-0208
EPA Comment ID: 28920
EPA Comment Code: 6140

Comment: Since approximately 1/3 of all drinking water treatment plants (DWTPs) in the United States use bulk hypochlorite for disinfection, hypochlorite should be considered as a source of perchlorate contamination in finished drinking water.[FN2: AWWA and Water Research Foundation. 2009. Hypochlorite - An Assessment of Factors That Influence the Formation of Perchlorate and Other Contaminants.] Sodium hypochlorite is a commonly used form of chlorine in drinking water. Because the AWWA-WRF analysis demonstrated the potential to exceed some existing state standards and HRLs proposed by USEPA, the results of this study should be reviewed when finalizing the regulatory determination, and also included in the discussion regarding existing and future drinking water disinfection practices.

Response: EPA is aware of this study and agrees that it should be considered in developing the NPDWR.

Comment: APPENDIX B

INITIAL REVIEW OF HOPONICK ET AL., 2009

Initial Review of: Hoponick JR, Melillo PR, Visser NT and Henshel DS. 2009. "Examining the Correlation between Perchlorate Concentrations in California Drinking Water and Low Birth Weight Percentage Using Population-Scale Regression Analysis," obtained from C. Matthews, Contractor, US EPA, Office of Environmental Information, EPA Docket Center, EPA Docket OW-2009-0297-0492, received via email on September 30, 2009.[FN1: http://www.regulations.govisearch/Regs/contentStreamer?objectId= 0900006480a27182&disposition=attachment&contentType=xml]

This document (Hoponick et al., 2009) appears to be a manuscript that has been submitted for publication. The study is an ecological epidemiological study, and is short in length. The authors evaluate the association between the mean perchlorate concentration measured in groundwater wells in 13 counties in California (measured between 1997 and 2004), and the percent of neonatal births with low birth weight (LBW), coded by zip code from 1993 to 2002. Zip code data sets for percent of births with LBW for each year were "averaged to the county level by averaging all data within each county." Based on this evaluation, the authors conclude that "log perchlorate data are significantly correlated with LBW for all years" and that "the increase is relatively linear from the lowest detectable perchlorate levels (3.3 ppb) to about 10 ppb, where the response appears to saturate." They further conclude, "Log perchlorate data also significantly positively correlates with TSH level for 1998, the only year for which TSH data was available."

An initial analysis of the manuscript was conducted using information derived from the manuscript. The source of data and an analysis of the methods and conclusions is provided below. Comments are divided into the following categories: data related to perchlorate concentrations in drinking water, data related to LBW, data related to neonatal TSH, and discussion of confounding factors.

EPA should review the scientific basis of this manuscript to assure itself that the data are reliable. Upon request, additional information can be provided. What might be useful is to review a recently published paper which reports no effect on birth weight, head circumference, and body length associated with perchlorate exposure (Blount et al., 2009). Briefly, the following is noted regarding the manuscript.

Perchlorate Concentrations in Drinking Water

Hoponick et al. (2009) conducted statistical analyses using the mean concentrations of perchlorate in drinking water,[FN2: The paper alternatively calls the water source either "groundwater wells" or "drinking water wells."] collected between 1997 and September 9, 2004, and averaged across each of 13 counties. The authors present mean concentrations for any California county that "contained two or more perchlorate detections from at least one drinking water source since 1997." Data were obtained from the California Department of Health Services website: http://www.cdph.ca.govicertlic/drinkingwater/Pages/Perchloratehistory.aspx. A downloadable MS Excel file of the data is here: http://www.cdph.ca.gov/certlic/drinkingwater/Documents/Perchlorate/Perchloratefo rwebearlyfindings.XLS.

Some observations about these data are as follows:

* The CDHS website only provides downloadable data for detects of perchlorate in water only. It is not clear from the manuscript whether the analysis considered nondetects in the calculation of mean perchlorate concentrations.

* Neither the CDHS website nor the manuscript indicate the analytical method that was used to measure perchlorate during this time. For example, a change in analytical method could impact the concentration data.

* The manuscript does not indicate the range of concentrations detected in the wells, the number and percentage of wells or water systems in which perchlorate was detected in each county, or how frequently perchlorate was detected in specific wells.

* The data obtained from CDHS shows that many wells were sampled repeatedly. However, the manuscript does not indicate how multiple detections at the same location were considered in the calculation of the county average.

* The manuscript does not indicate the extent to which sampled wells contribute to drinking water for the public in a given county, or whether water from wells was treated prior to distribution (but after sampling).

* Some of sample dates in the CDHS database cannot be discerned because they appear to be miscoded.

* The manuscript does not indicate how the timing of sample collection was assumed to relate to the association with LBW data.

* It appears that some average concentrations reported in the manuscript include data from wells designated in the CDHS database as "inactive" or "destroyed," and therefore would not contribute to drinking water that is distributed to the public. It is not clear how inclusion of these data is assumed to provide reliable measures of exposure.

Percent of Neonatal Births with Low Birth Weight (LBW)

Hoponick et al. (2009) report that data on neonatal birth weights were obtained from the California Department of Public Health (CDPH) for the years 1993 to 2002. The authors define "low birth weight" as a birth weight less than 2,500 grams (5.5 lbs.). The link provided in the paper redirects to here: http://ww2.cdph.ca.gov/programs/deodc/Pages/default.aspx. Annual data by zip code for the years 1993 to 2002 are available.[FN3: 1993:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip1993.xls 1994:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip1994.xls 1995:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip1995.xls 1996:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip1996.xls 1997:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip1997.xls 1998:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip1998.xls 1999:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip1999.xls 2000:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip2000.xls 2001:
http://wv2.cdph.ca.gov/data/statistics/Documents/birthzip2001.xls 2002:
http://ww2.cdph.ca.gov/data/statistics/Documents/birthzip2002.xls]

Some initial observations of these data are as follows:

* %LBW is lowest in 1996 for six of 13 counties and highest in 2002 for eight of 13 counties. The manuscript does not discuss these differences, or how they might relate to perchlorate exposure. For example, might there have been a change in the measurement or reporting method for birth weight?

* Sacramento County has 135 zip codes, but in 2002 (for example) the CDPH data only includes birth weight data for 49 zip codes. Further, the CDHS data includes only 34 water samples for perchlorate (from a total of 14 locations in five systems), after exclusion of data from inactive or destroyed wells. It is not clear how from the manuscript how data from these wells was extrapolated to assumed exposure across the county, or to specific zip codes, and how birth weight data for missing zip codes was considered. It appears that all individuals in the county were assumed to be exposed to the average perchlorate concentration computed from the available samples, and that the county average %LBW was based on the 49 zip codes for which data were available.

Neonatal TSH Data

The manuscript remarks "TSH data was obtained by contacting the CDHS directly, and 1998 was the only year CDHS provided." We were not able to find the data in the manuscript to support this statement.

Confounding Factors

The manuscript states, "The confounding factors data from 2003 was obtained from the California Interview Survey (CHIS) Database, which is operated by the University of California Los Angeles Center for Health Policy Research, in cooperation with CDHS and the Public Health Institute." The CHIS database is available (http://www.chis.ucla.edu/getdata.html). The only confounding variables reportedly considered by the authors were race and percentage of uninsured individuals. However, the literature on low birth weight is extensive and many other factors are known to influence birth weight including maternal health status, maternal age, smoking, alcohol/ drug use, prenatal care, maternal education level, and other socio-economic factors (Bailey and Byrom, 2007; Nobile et al., 2007). It appears that these factors were not evaluated.

Commenter Organization: Nevada Division of Environmental Protection (NDEP)
EPA Document ID: EPA-HQ-OW-2009-0297-0638
EPA Comment ID: 29100
EPA Comment Code: 6140

Comment: The August 19, 2009 Federal Register Notice indicates that EPA is considering using monitoring data from the State of Massachusetts to help characterize the distribution of very low perchlorate concentrations occurrences. Evidence needs to be provided to support the use of Massachusetts (or other discrete) monitoring data for the purpose indicated. EPA has not demonstrated how these data sets are representative of the nation as a whole. Model calibration should be conducted with robust data that are representative of the nation's water supply systems to make informed decisions regarding a national primary drinking water standard. Consequently, the NDEP recommends collection of new data for perchlorate in public water systems, coupled with the use of more sensitive analytical methods with greater specificity (EPA Method 331 or EPA Method 332). Newer, more sensitive analytical methods will provide more reliable and robust data, rather than trying to estimate values (< 4 ug/L) that are not part of the existing, outdated occurrence

data generated using a less sensitive analytical method (EPA Method 314). The referenced more sensitive methods have several method refinements (different column packing material, longer columns, mass spectrometry detectors) that lead to fewer false positives or false negatives and permit perchlorate analysis with reporting limits (detection limits) at or below 1 ug/L. These newer data are more robust and capable of multiple uses without limitations inherent in estimated data.

Response: EPA agrees that newer analytical methods are more sensitive. Information from a variety of sources will be used in developing the NPDWR. EPA is required to use the best available, peer reviewed science in its deliberations. The strengths and limitations will be considered as those deliberations proceed.

Comment: A Health Advisory for Perchlorate Will Undermine Cleanup Efforts

The establishment of a uniform federal standard is especially important to eliminate potentially conflicting state standards, particularly in cases of cross-boundary contamination. Merely publishing a health advisory for perchlorate, as EPA has proposed, will undermine expeditious cleanup of contaminated sites and regulation of discharges to interstate surface waters used to supply drinking water. A health advisory is not binding or enforceable, and does not ensure a uniform nationwide standard. Rather, it leads to a patchwork of different state standards and in the absence of a state standard, cleanup standards for individual sites that must be established through negotiation on a case-by-case basis.

Comment: Health Advisory

AWWA supports the EPA decision to issue a Health Advisory for perchlorate at the timeof the final determination. Health advisories provide important technical guidance to Federal agencies, State governments, and other public health officials on health effects, analytical methodologies, and treatment technologies. EPA should, in parallel, issue are vision of the "Assessment Guidance for Perchlorate" released by the Office of Solid Waste and Emergency Response (OSWER) on January 26, 2006, which defines the remediation goal for perchlorate in accordance with National Oil and Hazardous Substances Contingency Plan (National Contingency Plan, NCP), 40 CFR Part 300. In addition, any potential remediation action should consider all applicable or relevantand appropriate (ARAR) requirements under federal environmental or state environmental or facility siting laws.

Response: See response to comment ID 28479 under comment code 6200. A Health Advisory will no longer be needed.

Commenter Name: Ed Thomas

EPA Document ID: EPA-HQ-OW-2008-0692-1260
EPA Comment ID: 20624
EPA Comment Code: 6200

Comment: In the preliminary determination, EPA has indicated that States that are known to have perchlorate concentrations at or above the HRL should develop their own regulations, and has stated its intent to provide the States with a Health Advisory Level at the same time it finalizes this determination. We wish to state for the record that we will ask the State of New York for an enforceable MCL to be adopted. The Long Island Water Conference's member suppliers are fully supportive of science-driven regulations that are most protective of public health, and to that end have in some cases voluntarily installed treatment or modified operational practices to reduce the use of wells containing perchlorate.

Response: See response to comment ID 28479 under comment code 6200.

Commenter Name: James Taft
Commenter Organization: Association of State Drinking Water Agencies

EPA Comment ID: 20635
EPA Comment Code: 6200

Comment: A Health Advisory is step one - If the Agency is not going to develop a full national regulation, it needs to provide adequate support for those entities (water systems and states) that are going to respond at the local level. In the Federal Register notice, EPA committed to publishing a health advisory for perchlorate at the time of the final determination in order to provide information regarding potential health risks from perchlorate-contaminated drinking water. States fully support this action and recommend that the Agency provide the health advisory as soon as possible. While this may be enough to help states and water systems determine when perchlorate is approaching levels of health concern, it will not provide the level of technical support necessary for states and water systems to address perchlorate contamination problems.

Response: See response to comment ID 28479 under comment code 6200.

EPA Comment ID: 21102
EPA Comment Code: 6200

Comment: IX. EPA Should Make Conforming Changes to its Regulation and Policies Consistent with this Determination

At the same time of its final determination, EPA should maintain its March 2006 guidance for use by EPA regions and states, but update it with the new Health Advisory, if the decision is made to set one. The RfD is a conservative safe dose as has been noted throughout our comments. The current guidance allows state and local officials to factor in site-specific considerations and populations as opposed to making local decisions guidance data based upon nationally representative exposure data.

Issuing a health advisory and revised guidance at the same time as the agency issues a final determination provides a strong clear message from EPA headquarters to EPA regions as well as state and local public health officials on the final federal policy related to perchlorate. It brings to close any uncertainty at the federal level on the issue, thereby providing state and local officials with regulatory certainty and allowing them to move forward in addressing site-specific contamination.

Response: See response to comment ID 28479 under comment code 6200. A Health Advisory will not be needed.

EPA Comment Code: 6200

Comment: Based on the occurrence, health risk, and related findings presented in the Agency's analysis we also believe that a health advisory is appropriate. It is evident that perchlorate is a problem in specific targeted areas. A health advisory will provide the acceptable levels that are safe for local communities with contaminated source water.

Response: See response to comment ID 28479 under comment code 6200.

Comment: - Where Perchlorate is a problem, it is important that EPA provide resources to those states to appropriately and consistently respond. The first step should be for EPA to establish a health advisory that can be used to identify potential problems at the local level.

Response: EPA has determined the need to regulate perchlorate and will develop a NPDWR. As a result, a health advisory will not be necessary.

Commenter Name: James D. Taft
Commenter Organization: Association of State Drinking Water Administrators
EPA Document ID: EPA-HQ-OW-2009-0297-0525
EPA Comment ID: 28505
EPA Comment Code: 6200

Comment: A Health Advisory is step one - If the Agency is not going to develop a full national regulation, it needs to provide adequate support for those entities (water systems and states) that are going to respond at the local level. In the October 2008 Federal Register notice, EPA committed to publishing a Health Advisory for perchlorate at the time of the final determination in order to provide information regarding potential health risks from perchlorate- contaminated drinking water. States fully support this action and recommend that the Agency finalize the interim January 2009 health advisory as soon as possible. ASDWA also recommends that EPA prepare educational materials to help states and water systems use the Health Advisory to educate the public about perchlorate in the systems where it is detected.

Thank you for your consideration of these comments. Please contact me at 703-812-9507 or jtaft@asdwa.org if we can provide additional information or if any clarification of these comments is needed.

Sincerely, James D. Taft Executive Director

Response: See response to comment ID 28479 under comment code 6200.

EPA Comment ID: 28832
EPA Comment Code: 6200

Comment: In addition, if EPA chooses to update its health advisory, AMWA recommends that the agency take care to explain the difference between perchlorate and other chemical compounds. Perchlorate is an endocrine disruptor and in the words of one peer reviewer,

"However, as noted above, what is still needed at the beginning of the document is a brief overview of the toxicokinetics of perchlorate, iodine as an essential element for the synthesis of thyroid hormones, why thyroid hormone sufficiency is important, what homeostasis is - perchlorate affects a self-regulating system which has evolved numerous feedback mechanisms to compensate for deficiency induced by inadequate intake, iodine uptake inhibition, illness and that within the homeostatic range, which is robust in humans, this system is successful. [The same would be true for excess.] In other words, the biological impacts of perchlorate are very different from those for chemical compounds which have direct target organ toxicity and/or do not directly affect the availability of an essential element for which homeostasis occurs." (EPA, 2008. Comment- Response Summary Report. Peer Review of Drinking Water Health Advisory for Perchlorate, page 7).

Response: EPA agrees that this suggested information should be incorporated into support documentation for the impending NPDWR.

EPA Comment Code: 6210

Comment: However we wish to point out that those States that need to develop their own standards, potentially as many as 26 according to the preliminary determination, will need to make other complex decisions beyond establishing an MCL. EPA knows the importance of a fully-formed regulation that is legally defendable. To that end decisions will need to be made as to acceptable analytical methodologies, best available treatment technology and treatment residuals disposal, minimum analytical frequencies, and perchlorate occurrence processes. It should also be recognized that companion regulations will need to be developed to identify and restrict industrial applications and storage of chemicals containing perchlorate. Unmeasured perchlorate may exist in products in common use, yet the users may be unaware of a potential concern. As previously stated, many perchlorate detections do not trace to known sources.

Therefore we do wish to state our concern that states may lack the resources to develop a robust regulatory response to their individual perchlorate issues. We would respectfully request that EPA's guidance to the states should also incorporate a Federal resource commitment to the other aspects of the regulatory problem that the states will have to face. EPA should also continue to be a clearing house of information on perchlorate and commit research dollars to encourage the development of economically viable treatment alternatives, and to better understand perchlorate occurrence.

The Conference appreciates your consideration of these comments and looks forward to seeing the continued development of this important regulation.

Very truly yours, Kenneth S. Claus Chairman, Long Island Water Conference

Response: See the response to comment code 6120. EPA acknowledges commenter's concern about decisions that will need to be made as to acceptable analytical methodologies, best available treatment technology and treatment residuals disposal, minimum analytical frequencies, and perchlorate occurrence processes. These issues are factors that EPA will consider when developing a NPDWR for perchlorate. Upon promulgating a NPDWR, EPA will provide States and public water systems with information in regards to perchlorate treatment techniques. EPA acknowledges commenter's statement "…It should also be recognized that companion regulations will need to be developed to identify and restrict industrial applications and storage of chemicals containing perchlorate." However this subject matter pertains to EPA's RCRA regulations and falls outside of the scope of this regulatory action.

Pursuant to SDWA section 1412(b)(4)(E), 42 USC 300g-1(b)(4)(E), when EPA publishes a NPDWR establishing an MCL, the Administrator must list technologies, treatment techniques, and other means that the Administrator finds feasible for meeting the MCL, and:

The Administrator shall include in the list any technology, treatment technique, or other means that is affordable, as determined by the Administrator in consultation with the States, for small public water systems serving--

(I) a population of 10,000 or fewer but more than 3,300;

(II) a population of 3,300 or fewer but more than 500; and

(III) a population of 500 or fewer but more than 25;

and that achieves compliance with the maximum contaminant level or treatment technique, including packaged or modular systems and point-of-entry or point-of-use treatment units.

EPA Comment ID: 20636
EPA Comment Code: 6210

Comment: Provide additional guidance to support states and water systems - In addition to the health effects, systems will need to know what treatments are effective for various types of source water and levels of perchlorate. Systems will also need information to help them evaluate non-treatment alternatives to perchlorate control (if available). ASDWA would be willing to work with EPA and other partners to determine what supporting materials should be developed.

Thank you for your consideration of these comments. We feel that perchlorate is somewhat of a special case due to its high profile and potential for causing adverse health effects and therefore deserves something beyond just a health advisory to support state drinking water programs. We hope the Agency will be willing to take these additional steps and we are ready to help develop a reasonable plan. Please contact me at 703-812-9507 or jtaft@asdwa.org if we can provide additional information or if any clarification of these comments is needed.

Sincerely, James D. Taft Executive Director

Response: EPA agrees and has decided to regulate perchlorate in drinking water. See response to comment code 6120. Pursuant to statutory requirements, EPA intends to publish and seek public comment on technology, treatment techniques, and other means which the Administrator finds to be feasible for purposes of meeting the proposed maximum contaminant level. The proposed regulation will also include an assessment of alternative treatment techniques that EPA is considering.

EPA Comment ID: 28480
EPA Comment Code: 6210

Comment: - Where Perchlorate is a problem, it is also important that EPA provide technical information on effective treatment options for various source waters and levels of Perchlorate.

Response: EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. This action initiates the process to establish a national primary drinking water regulation (NPDWR) for perchlorate. EPA will provide an evaluation of feasible treatment technologies and small system compliance techniques as part of the proposed NPDWR.

Commenter Name: James D. Taft
Commenter Organization: Association of State Drinking Water Administrators
EPA Document ID: EPA-HQ-OW-2009-0297-0525
EPA Comment ID: 28504
EPA Comment Code: 6210

Comment: Additional issues - In closing, we would like to recap some of our previous comments related to the regulation of perchlorate. These are still valid points and need to be considered, regardless of what final determination is made.

Regardless of EPA's regulatory decision, states will need to act - Even if EPA does not adopt a national regulation of perchlorate, the public will likely demand a response to detections of elevated levels of perchlorate - particularly, in light of the notoriety associated with this contaminant. In states where there are detections of perchlorate at levels of concern, drinking water programs need to be able to respond appropriately so that public health can be protected. At a minimum, states will need to assist individual water systems with the specific actions needed to control perchlorate. Information is needed from EPA on risk characterization and risk management as well as treatment options and alternative control measures to support state efforts. In some cases, a state may decide that perchlorate is common enough in their source waters that they are interested in developing statewide measures, whether it is a formal monitoring program or a state specific MCL. We believe the Agency has data and expertise that can help support these actions.

Response: EPA agrees and has decided to regulate perchlorate in drinking water. See response to comment code 6120 and response to comment ID 20634 under comment code 6130.

Commenter Name: Danielle Blacet
Commenter Organization: Association of California Water Agencies
EPA Document ID: EPA-HQ-OW-2009-0297-0208
EPA Comment ID: 28921
EPA Comment Code: 6210

Comment: 3) Colorado River implications

As USEPA is aware, much of Southern California depends on a reliable water supply from the Colorado River, and our members actively participate with other Colorado River basin states to help ensure the delivery of a quantity and quality of water that will meet our environmental, urban and agricultural needs. This situation has become even more critical with the recent droughts in the Colorado River basin and California.

ACWA strongly recommends that during its science-based review and ultimate regulatory determination for perchlorate, USEPA remains cognizant of the sources and impacts from interstate perchlorate contamination to all California utilities, particularly those that rely on the Colorado River. This especially is relevant to agricultural use of Colorado River water and concentration of perchlorate in produce shipped nationwide. We would like to work with USEPA on ways to address this very important issue.

Response: EPA has determined that regulation of perchlorate in drinking water systems presents a meaningful opportunity to reduce health risk for persons served by public water systems. See response to comment code 6120. This action initiates the process to establish a national primary drinking water regulation (NPDWR) for perchlorate. In developing the proposed national primary drinking water standard, EPA will consider the degree to which perchlorate is present in public water supplies in all systems throughout the U.S. EPA intends to publish the proposed NPDWR for public comment along with health risk reduction and cost analysis, feasibility analysis and other analyses required for regulatory development under the SDWA. EPA will consider comments on the proposed NPDWR and then promulgate the final regulation.

EPA Comment Code: 6300 EPA's intention to revise guidance on clean-up levels (preliminary remediation goals)

Response to Code 6300: While EPA recognizes that perchlorate has been a contaminant of concern at a number of sites that have (or may in the future) require cleanup, it is not appropriate for the Agency to establish national primary drinking water regulations for the purpose of establishing cleanup levels at contaminated sites. Rather, the Safe Drinking Water Act specifies the criteria which compels regulation of a contaminant. EPA must determine that the contaminant meets three criteria: 1) the contaminant may have an adverse effect on human health, 2) the contaminant is known to occur or there is a substantial likelihood that the contaminant will occur in public water systems with a frequency and at levels of public health concern, and 3) in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for the reduction of health risks from perchlorate for persons served by public water systems. We would note, however, that on January 8, 2009, EPA issued guidance that revised the preliminary remediation goal (PRG)[Footnote] for perchlorate in soil from 24.5 ug/L to 15/ug/L, which states that where no federal or state applicable or relevant and appropriate (ARAR) requirements exist under federal or state laws, 15 ug/L is recommended as the PRG for perchlorate when making CERCLA site-specific cleanup decisions where there is an actual or potential drinking water exposure pathway (http://www.epa.gov/fedfac/documents/perchlorate_memo_01-08-09.pdf). Depending on EPA's final decision regarding a national primary drinking water standard for perchlorate, the Agency may modify this guidance.

Footnote: PRGs are not cleanup levels, but are specific statements of desired endpoint concentrations or risk levels (55 FR 8713 (March 8, 1990)) that are conservative, default endpoint concentrations used in screening and initial development of remedial alternatives before consideration of information from the site-specific risk assessment.

Commenter Name: Diane VanDe Hei
Commenter Organization: Association of Metropolitan Water Agencies (AMWA)
EPA Document ID: EPA-HQ-OW-2007-0068-0166
EPA Comment ID: 20276
EPA Comment Code: 6300

Comment: AMWA believes that factors other than those discussed in the notice need to be considered. The contamination of water supplies by perchlorate is on-going, since perchlorate is still in use at various DoD sites, airfields and rocket manufacturing facilities. In addition, because there is no cleanup standard, perchlorate that has entered the soil and contaminated aquifers will likely spread, leading to additional impacted sites.

When a contaminant is polluting drinking water supplies and the lack of a standard is impeding pollution prevention and cleanup, then an appropriate course of action is needed. Several of the contaminants in the notice deemed appropriate for a determination not to regulate are pesticides that have not been produced or used for decades and have low and decreasing occurrence levels. Perchlorate, on the other hand, is still in use and is expected to have increasing occurrence levels as contamination migrates from soils to ground water aquifers, potentially resulting in impacts on increasing numbers of water systems - clearly a call for action.

Response: See response to comment code 6300. The Agency has determined that the three SDWA criteria for regulatory determination have been met for perchlorate. See response to commend code 6120.

EPA Document ID: EPA-HQ-OW-2008-0692-1525
EPA Comment ID: 20445
EPA Comment Code: 6300

Comment: Cleanup Standards

AMWA agrees with the agency that guidance regarding perchlorate and cleanup levels under the National Oil and Hazardous Substances Contingency Plan (National Contingency Plan, NCP) should be revised downward from the present preliminary remediation goal (PRG) of 24.5 ppb. AMWA believes, however, that an appropriate PRG to protect drinking water and it users should assume that contaminated water sources would be used as drinking water. Perchlorate contaminated sites should be cleaned up to some fraction of the HRL (such as two-thirds or 10 ppb) so that any levels consumed are reliably and consistently below the HRL.

Since the recommended PRG generally is the starting point for determining appropriate site-specific cleanup levels, AMWA believes it is appropriate to start at levels that allow a margin of safety with respect to the HRL to account for the variable nature of continuing contamination and occurrence fluctuations. The level could then be adjusted up or down depending upon the site specifics. The PRG based on the HRL should not supplant more stringent state standards.

Response: See response to comment code 6300.

Comment: Historical industrial operations have impacted the aquifer in the PGA North Superfund Site with TCE and perchlorate. The EPA Region 9 is currently overseeing a private party financed cleanup of the TCE impacted groundwater at the site. The remedy consists of several independent groundwater pump-and-treat systems. The treated water is either used as an irrigation supply or reinjected into the aquifer. Future remedies being considered to address the currently expanding TCE plume may entail providing the treated water for drinking water purposes. Where groundwater is being reinjected to the aquifer, EPA Region 9 is requiring the private party to treat for perchlorate as well as TCE in order to avoid aquifer degradation in areas not impacted by the plume. However, no treatment is required for water used as an irrigation supply. Since perchlorate, unlike TCE, has no established standard, EPA 9 is relying on guidance and "To Be Considered" criteria to require treatment of reinjected water at the PGA-North Superfund Site. Without the strength of a promulgated standard, we are concerned that EPA Region 9 will not be able to ensure that future remedies require perchlorate treatment. Further, guidance levels and To Be Considered criteria may

not provide EPA Region 9 the necessary authority to require that the responsible party implements an effective remedy to address the historical perchlorate contamination in the aquifer-our future water supply.

Response: See response to comment code 6300.

Commenter Name: Mic Stewart
Commenter Organization: Metropolitan Water District of Southern California
EPA Document ID: EPA-HQ-OW-2008-0692-1784
EPA Comment ID: 20664
EPA Comment Code: 6300

Comment: * Applicable or Relevant and Appropriate Requirements (ARARs) - While California has a drinking water MCL of 6 ppb for perchlorate, Metropolitan suggests that given any decision by the EPA not to regulate perchlorate, the ARARs called for in regulatory cleanup be set at the drinking water standard in states with an MCL for perchlorate. This would provide cleanup guidance for contaminated sites.

* Site specific cleanup levels - EPA states that the Health Advisory value can be used as a "to be considered value" for developing cleanup levels for perchlorate contaminated sites (i.e., Superfund). The Health Advisory value that should be stipulated in the final health advisory document will be set at a level to provide protection to the population. Sites that are potential sources of drinking water, or impact sources of drinking water, should be required to treat to a level that protects the population. A "to be considered" criteria for clean-up levels is not adequate to provide protection to the public.

Metropolitan appreciates this opportunity to provide input on the proposed regulatory determination for perchlorate and asks that EPA carefully consider these comments before publishing the final rule. Please contact me at (213) 217-5696 if you have any questions, or if I can provide additional information.

Very truly yours, Mic Stewart, PhD Manager, Water Quality Section

Response: See response to comment code 6300. The Agency has determined that the three SDWA criteria for regulatory determination have been met for perchlorate. See response to commend code 6120.

Water Docket Environmental Protection Agency Mailcode: 2822T 1200 Pennsylvania Avenue, NW Washington, DC 20460

SUBJECT: Comments on the Drinking Water: Percholorate Supplemental request for Comments Docket ID No. EPA-HQ-OW-2009-0297

The Southern Nevada Water Authority (Authority) submitted detailed comments, dated September 17, 2009, on the preliminary regulatory determination for perchlorate as listed in the August 19, 2009 Federal Register (74FR41883). We would like to submit the following additional comments regarding the Authority's commitment to ensure that perchlorate clean-up efforts continue along the Las Vegas Wash (Wash) upstream from Lake Mead.

As outlined in our comments previously submitted, perchlorate clean-up efforts in the Wash have significantly decreased the levels of perchlorate in Lake Mead and the lower Colorado River system. Tronox, Inc., (Tronox) owns the facility in Henderson, Nevada that produced perchlorate from 1952-2002. The site is the source of perchlorate contamination of groundwater that enters the Wash (which empties into the Colorado River). Currently, the contaminated water is intercepted at the Wash, treated in a remediation system financed by Tronox, and discharged into the Wash. The system is operated at the direction of the Nevada Division of Environmental Protection (NDEP), which estimates the current annual cost of operation at $6,000,000 with a potential remediation span of 100 years. On January 12, 2009, Tronox filed a petition for reorganization in United States Bankruptcy Court for the Southern District of New York.

The Authority, in order to actively participate in the litigation and to protect its strong interest in continued groundwater remediation and eventual elimination of the source of perchlorate contamination, hired the New York City bankruptcy firm of Kramer Levin Naftalis & Frankel. The Authority has filed a proof of claim, is examining the terms of a proposed sale of the Henderson site, and is working in concert with the Metropolitan Water District of Southern California (MET) and the Central Arizona Water Conservation District (CAP) to ensure that remediation efforts receive an adequate accounting and future funding.

To summarize, the Authority in concert with the NDEP and our partners, CAP and MET, are committed to ensuring the clean-up of perchlorate continues along the Wash. If you have any questions regarding our comments, please contact me directly at (702) 862-3707.

Sincerely, Kay Brothers Deputy General Manager Engineering and Operations

Response: No response necessary for this comment.

EPA Comment Code: 6400 EPA's decision to subject updated PBPK model to peer review during comment period (in the October 2008 FR Notice)

Response to Code 6400: EPA reviewed, modified, and applied the perchlorate PBPK models, which were originally developed by Merrill et al. (2005) for adults and Clewell et al. (2007) for other life stages, to estimate the iodide uptake inhibition in the thyroid for each life-stage (73 FR 60262). Estimated ingestion rates were then used to estimate the internal dose and resulting iodide uptake inhibition for several life stages, including susceptible populations (e.g., pregnant women and their fetuses, as well as breast-fed and bottle-fed infants).

The draft report, "Inhibition of the Sodium-Iodide Symporter by Perchlorate: An Evaluation of Lifestage Sensitivity Using Physiologically-based Pharmacokinetic (PBPK) Modeling," underwent a formal external peer review by eight experts in accordance with EPA guidance concurrently with the public comment period. Based on the external peer review comments, the models and report were revised. The final report, peer review report, and a summary of peer review comments and EPA responses are available at http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=199347.

In the August 2009 notice, EPA stated that it was re-evaluating how best to incorporate the PBPK modeling analysis into its evaluation of perchlorate — if at all. The Agency sought comments on ways to use the PBPK modeling analysis to inform the regulatory determination.

After further consideration of the peer review and public comments, EPA concludes that the PBPK modeling analysis, in the context of the perchlorate regulatory determination, is useful in examining which life stages are most susceptible to the effects of perchlorate. However, because of the stated limitations, EPA has decided the model does not directly bear on the current decision regarding the need for a NPDWR for perchlorate. EPA is continuing to evaluate whether the model could be used in setting a NPDWR for perchlorate.

Comment: November 10, 2008

Water Docket U.S. Environmental Protection Agency Office of Water Docket (Mailcode 2822T) 1200 Pennsylvania Ave. NW Washington, DC 20460

RE: Drinking Water: Preliminary Regulatory Determination on Perchlorate; Docket EPA-HQ-OW-2008-0068

Dear Water Docket:

AMWA appreciates the opportunity to comment on the preliminary regulatory determination for perchlorate as listed in the October 10, 2008 Federal Register (73 FR 60262). AMWA strongly

supports the process required by the 1996 Amendments of the Safe Drinking Water Act that places a strong emphasis on science and focuses on contaminants which: may have an adverse effect on humans, occur or are likely to occur at levels of public health concern and provide a meaningful opportunity for health risk reduction.

Members of Congress, the Administrator and the public have all weighed in on the need to regulate perchlorate. Concern over the lack of a regulatory path forward coupled with differing interpretations of the available scientific information has led to significant controversy. In such an environment, decisions need to be supported by peer reviewedscience to garner general acceptance. Accordingly, AMWA has several recommendations for the agency concerning peer review, review by the National Academy of Sciences (NAS), retention on the Contaminant Candidate List (CCL), the need for a strong cleanup standard, and other considerations. The remainder of these comments will address each in turn.

Peer-Review

In the Federal Register Notice, EPA expresses its intention to subject several key scientific points used in the decision process to peer-review before finalizing the determination. The agency notes that adjustments have been made to a previously peer-reviewed physiologically based pharmacokinetic (PBPK) model for predicting iodide uptake for several sensitive subpopulations. Additionally, the agency feels that it is pertinent to have a peer-review panel consider the appropriateness of the model for addressing non-adult populations. AMWA agrees that such reviews are appropriate and necessary. However, the agency should assure that peer review panel questions are posed so that the usefulness of the model is explored with specific regard to the most sensitive subpopulations. Specifically, detailed comment should be solicited on whether the lack of data on early fetal radioactive iodide uptake inhibition would be expected to affect the agency's determination that a Health Reference Level (HRL) of 15 ppb is protective of pregnant women and fetuses.

Response: See response to comment code 6400.

Comment: FROM: Robert A. Howd California Environmental Protection Agency, Office of Environmental Health Hazard Assessment

November 7, 2008

Water Docket Environmental Protection Agency Mailcode: 2822T 1200 Pennsylvania Ave., NW Washington, DC 20460

Subject: Comments to Docket ID No. EPA-HQ-OW-2008-0068

To Whom It May Concern:

Thank you for providing the opportunity to comment on the Federal Register announcement of Friday, October 10, 2008, titled "Drinking Water: Preliminary Regulatory Determination on Perchlorate" (FR 73, no. 198, pp. 60262- 82). These comments were prepared by the Water Toxicology Section of the California Office of Environmental Health Hazard Assessment.

II(D), p 60265. EPA states that its regulatory determination on perchlorate has been based in part on a PBPK model with adjustments made by EPA that have not been peer reviewed (U.S. EPA, 2008). Some of the adjustments, including perchlorate inhibition of fetal iodide uptake, are critical to the interpretation. We recommend that such a peer review, plus opportunity for public comment on the model, be carried out before EPA publishes its final determination on perchlorate.

Response: See response to comment code 6400.

Comment: November 5, 2008

The Honorable Stephen L. Johnson Administrator U.S. Environmental Protection Agency 1200 Pennsylvania Avenue, N.W. Washington, D.C. 20460

Dear Administrator Johnson:

Thank you for your memorandum of October 20, 2008, requesting that the Science Advisory Board (SAB) undertake a study to provide advice on how EPA can strengthen scientific assessments, better communicate the results of assessments, and integrate natural science assessment with economic and social assessments to support EPA decision making. I had the opportunity to discuss the request with my colleagues this week at a public advisory meeting of the chartered SAB. We will undertake this effort with the goal of providing advice to the new EPA Administrator within a year.

At our public meeting on October 28, 2008, the chartered SAB also discussed a draft report from the SAB's Drinking Water Committee on EPA's Draft Third Drinking Water Contaminant Candidate List (CCL3). The Committee's draft report highlighted its recommendation that perchlorate is one of four chemicals that "should be a high priority for consideration by the Agency, because there is a higher degree of certainty about their toxicity, occurrence, and treatability."

The SAB is also aware that EPA published a Drinking Water: Preliminary Regulatory Determination on Perchlorate in the Federal Register on October 10, 2008 (73 FR 60262-60282). That notice provides a preliminary determination that "a national primary drinking water regulation (NPDWR) for perchlorate would not present 'a meaningful opportunity for health risk reduction for persons served by public water systems'" and provides a thirty-day public comment period. The notice also states that EPA plans to issue a final regulatory determination by December 2008. It should be

noted that this preliminary determination relies on the use of a dosimetric model which is now undergoing letter peer review, and thus, its soundness will not be publicly vetted.

Given perchlorate's wide occurrence and well-documented toxicity to humans, the SAB strongly believes that there must be a compelling scientific basis to support a determination not to regulate perchlorate as a national drinking water contaminant. The quality of the scientific foundation for EPA's decisions depends on peer review, which brings a variety of scientific perspectives to bear on critical components of EPA's decisions. Where science assessments have been conducted with the benefit of external scrutiny, the end products have been better able to support the policy making process. This view is very much aligned with the perspectives expressed in your memorandum to the SAB.

Response: Administrator Stephen Johnson replied to the SAB on January 9, 2009. The letter is available in EPA's docket ID No. EPA-HQ-OW-2009-0297 for this notice. which is located in docket EPA-HQ-OW-2008-0692.

EPA Comment Code: 6400

Comment: We are particularly concerned that the preliminary determination was issued before peer reviews of the physiologically-based pharmacokinetics (PBPK) model used to derive the health reference level AND the health reference level itself were available. Given widely varying analysis of existing data, these peer reviews could shed important light on the Agency's deliberations. We urge the Agency to reconsider its determination and to take the time necessary to fully consider setting a federal standard for perchlorate in drinking water.

I appreciate the opportunity to weigh in on this important decision and am happy to provide more information if required.

Sincerely, Lynn Thorp, National Campaigns Coordinator CC: Eric Burneson, OGWDW

Response: See response to comment code 6400.

EPA Comment ID: 20949
EPA Comment Code: 6400

Comment: The Post hoc Application of PD Modeling Inappropriately Allows the Exceedence of the RfD

EPA has chosen to use a novel approach in setting a risk-based health risk level for perchlorate by using physiologically based pharmacokinetic modeling to justify the exceedence of the reference

dose at a level ranging from 2 - over 5%. In doing so, EPA would allow perchlorate exposures to attain unacceptably high levels.

The model that EPA is using has not yet completed peer review, so that stakeholders have no assurance that the model design is appropriate for the task at hand. EPA should wait until the peer review process is complete before applying this model for official purposes as the peer review process could uncover important limitations of the model. For instance, while the model reports that predicted perchlorate blood levels would be higher in the fetus, lactating women and neonates, it is not clear if the model includes new information regarding the impact of TSH on NIS uptake of perchlorate (e.g., Tran et al. 2008 is not cited in the EPA document describing the model, EPA/600/R-08/106A), nor is it known how this new information might affect the modeling results. A peer review panel would be in the best position to weigh in on questions such as this one.

It is also not clear if the model has been validated using responses of sensitive populations that include sub-optimal iodine intake. Given the documented impact on response to perchlorate exposure, this is would be an important step in the validation process. The model extrapolations were reportedly compared to data from the Chilean population, which as noted above, was fully iodine sufficient. Considering the demographics of iodine insufficiency in the US, it is imperative that the model extrapolations also be compared with data from a population that is not iodine sufficient.

Comment: Despite these conclusions, only one week later and without waiting for the report to be peer-reviewed and available for public comment, EPA announced that it would not regulate perchlorate in drinking water. Although the Federal Register notice does report the staff conclusions, it contradicts them concluding that "EPA believes drinking water with perchlorate concentrations at or below the HRL of 15 ug/L is protective of all subpopulations."[FN52: Id. at 60280]

Response: EPA has decided to regulate perchlorate in drinking water. See response to comment code 6120 and response to comment code 6400.

EPA Comment Code: 6500

Comment: We are writing on behalf of the American Thyroid Association (ATA) in response to your request for comments (Fed Reg 74:41883, 08/19/09) regarding EPA's perchlorate regulatory determination. The ATA represents the largest and most established group of physicians dedicated to the study of the thyroid gland and its disorders.

Decreases in maternal thyroid hormone associated with even mild iodine deficiency may have adverse effects on the cognitive function of offspring.1,2,3 It has recently been suggested that mild iodine deficiency may also be associated with thyroid deficiency resulting in attention deficit and hyperactivity disorders in offspring.4 Iodine deficiency affects over 2.2 billion individuals worldwide (38% of the world's population), and iodine deficiency is the leading cause of thyroid failure causing preventable mental retardation worldwide.5

Over the last few decades, iodine intake in the United States has declined.6 Although iodine intake remains sufficient for the general U.S. population, there have been concerns in recent years that some pregnant women and women in their childbearing years may have inadequate iodine intake.7,8 For this reason, in 2006 the ATA published recommendations for iodine supplementation of all U.S. pregnant and lactating women.9 These guidelines have not been widely adopted, and the availability and frequency of use of iodine-containing prenatal multivitamin supplements among pregnant U.S. women remains suboptimal.10,11

Response: See response to comment ID 28842 under comment code 6500.
As discussed in detail in the final regulatory determination, EPA has found that perchlorate may have an adverse effect on human health.

Comment: We would strongly urge that, whatever the EPA determines about the need for regulation of perchlorate in drinking water, attention should be paid to ensuring adequate iodine nutrition in the U.S., particularly among women who are pregnant or lactating.

Thank you for this opportunity to comment upon and contribute to your regulatory determination for perchlorate. Clearly, there is more need for studies in this area in order to obtain greater clarity.

EPA Document ID: EPA-HQ-OW-2009-0297-0664

EPA Comment ID: 28549
EPA Comment Code: 6500

Comment: It is key to this discussion that exposure to perchlorate is only potentially problematic for individuals with iodine deficiency. There is no evidence[FN1: United States Food and Drug Administration. Perchlorate Questions and Answers. http://www.fda.gov/Food/FoodSafety/FoodContaminantsAdulteration/ChemicalContaminants/Perchlorate/ucm077572.htm] that iodine deficiency is a widespread problem in the United States, and that only individuals who are on restrictive diets or purposely avoid iodine consumption are at risk for such a deficiency. While there is no evidence that iodine deficiency is a widespread problem in the US, women of child-bearing age and pregnant women are theoretically more at risk for effects of perchlorate consumption. Because inadequate iodine consumption during pregnancy can lead to negative birth outcomes, any further reduction uptake by the thyroid from exposure to perchlorate could pose a risk. While there is no evidence of widespread iodine deficiency in women of child-bearing age or pregnant women, this subpopulation could be targeted with education about diet during pregnancy and appropriate prenatal care that stresses the importance of adequate iodine consumption during pregnancy.

In conclusion, we point to the EPA Office of Inspector General's (OIG) draft review[FN2: United States Environmental Protection Agency. Office Inspector General Scientific Analysis of Perchlorate. http://www.epa.gov/oig/reports/2009/20081230-2008-0010.pdf] of EPA's perchlorate assessment which emphasizes a number of important points that are relevant to this discussion. Specifically, the review points to the fact that other naturally occurring compounds found in food behave in a way that is similar to perchlorate. According to this review, regulating perchlorate in drinking water is unlikely to have any material impact on public health. We agree with the conclusion in OIG's draft that promoting adequate iodine intake is a superior approach than regulating perchlorate as a drinking water contaminant.

Because the public health concerns associated with potential perchlorate consumption can be addressed through education and dietary modifications in a small subset of the population, NASDA is very concerned that EPA not adopt an approach that would lead to consumer confusion, food scares, and potential financial devastation for American agricultural producers.

Sincerely, Stephen Haterius Executive Director

Response: See response to comment ID 28530 under comment code 6500. Perchlorate contamination is more widespread in foods than in drinking water; however, EPA does not believe that the widespread presence of perchlorate in food overrides the need for public health risk reduction for persons served by PWSs with perchlorate contamination. The Agency presented an extensive evaluation of dietary exposure to perchlorate in the October 2008 and August 2009 notices (73 FR 60262; USEPA 2008a and 74 FR 41883; USEPA 2009b). EPA has used this dietary exposure data to account for the relative source contribution (RSC) of perchlorate from food to estimate the range of levels of public health concern. EPA recognizes that a drinking water regulation would not eliminate total perchlorate exposure, but believes that the reduction in perchlorate exposure in drinking water presents a meaningful opportunity for health risk reduction for persons served by PWSs contaminated by perchlorate. EPA agrees that promoting iodide nutrition is good public health policy and may have a positive influence in reducing the iodide uptake inhibition effects associated with exposure to perchlorate. However, the Agency does not

think it is appropriate to rely on the promotion of iodide nutrition in this case, especially since these activities are outside of EPA's SDWA authority. As a result, while the health concerns associated with perchlorate may be addressed through other means, it is the Administrator's judgment that a standard limiting perchlorate in drinking water can reduce health risk, particularly to fetuses, infants and children.

Regarding the OIG report, while EPA acknowledges that nitrate and thiocyanate have the same mode of action as perchlorate, and that the effects of combined exposure to perchlorate, nitrate, and thiocyanate are additive, EPA does not believe there are sufficient scientific data currently available to assess and characterize the combined risk of these contaminants. EPA has committed to a drinking water strategy that outlines four principles to expand public health protection for drinking water (USEPA, 2010b). One of these principles is to address contaminants as groups. However, EPA does not believe that regulatory action to address perchlorate should be further delayed. Therefore, EPA intends to develop a proposed rule for perchlorate. At such time as a NPDWR is promulgated, EPA is required to review and revise, as appropriate, its drinking water standards at least every six years. Any revision must at least maintain or improve public health protection. When there are sufficient scientific data to assess the cumulative risks of perchlorate and other contaminants, EPA will review this information to evaluate whether any revisions of NPDWRs are appropriate.
EPA has determined the need to regulate perchlorate in drinking water. Care will be taken to communicate the implications of that regulation.

EPA Comment Code: 6500

Comment: For iodine, FDA found that each of the 14 age/sex groups, including infants, children, and women of childbearing age exceeded the average intake levels estimated by the NAS to meet requirements for healthy individuals.

In light of these findings, FDA continues to stand by its prior recommendation that consumers should not alter their infants' and children's diets or eating habits. Indeed, many of the foods at issue are major dietary sources of iodine and other nutritionally essential substances.

EPA's Calculation of the Relative Source Contribution for its 2008 Preliminary Regulatory Determination also Reveals that Perchlorate Exposure from Food is Below any Meaningful Level of Concern.

Response: EPA calculated potential alternative HRLs that were included in the August 2009 notice. These values incorporate and estimate perchlorate from food, deriving the potential alternative HRL such that only the water contribution of perchlorate would require adjustment to attain a tolerable perchlorate exposure from all sources. The Agency presented an extensive evaluation of dietary exposure to perchlorate in the October 2008 and August 2009 notices (73 FR 60262; USEPA 2008a and 74 FR 41883; USEPA 2009b). EPA has used this dietary exposure data to account for the relative source contribution (RSC) of perchlorate from food to estimate the range of levels of public health concern. EPA recognizes that a drinking water regulation would not eliminate total perchlorate exposure, but believes that the reduction in perchlorate exposure in drinking water presents a meaningful opportunity for health risk reduction for persons served by PWSs contaminated by perchlorate.

Commenter Organization: American Water Works Association (AWWA)
EPA Document ID: EPA-HQ-OW-2009-0297-0415
EPA Comment ID: 28842
EPA Comment Code: 6500

Comment: AWWA also concurs with the Agency's Inspector General [FN1: Wilson, M. 2008. Scientific Analysis of Perchlorate. US Environmental Protection Agency, Office of Inspector General. Available at http://www.epa.gov/oigearth/reports/2009/20081230-2008-0010.pdf] in stating that regulatory action under the Safe Drinking Water Act (SDWA) is not the appropriate or effective way to address the overarching public health issue - iodide deficiency. The National Research Council (NRC) assessment [FN2: National Research Council (NRC). 2005. Health Implications of Perchlorate Ingestion. National Academy Press, Washington, DC.] of perchlorate also recognized iodide deficiency as the larger public health issue.

Response: EPA based its final regulatory determination on a number of different factors including the careful consideration of public comments. Regarding correcting iodine deficiencies, the Food and Drug Administration and Centers for Disease Control generally conclude that there is sufficient iodine in the diet. Below are findings from FDA's Total Diet Study (2003-2004) that estimates the dietary intake of iodide for 14 age-sex groups (Murray et al., 2008) and CDC's National Health and Nutrition Examination Survey that measured perchlorate in the urine of study participants in (2003-2004, no data on < age 6). FDA's Total Diet Study findings: - Infants, 6-11 months, exceeded their Adequate Intake - Children and adult age/sex groups exceed their relevant Estimated Average Requirement CDC's National Health and Nutrition Examination Survey: - "This finding confirms the stability of the U.S. iodine intake and continued adequate iodine nutrition for the country in general." - "On the basis of median urinary iodine concentrations, iodine intake of women of childbearing age appears adequate."

EPA Comment Code: 7000 Miscellaneous Comments

Response to Code 7000: See response to comment code 6120 for a discussion of EPA's decision to regulate perchlorate in drinking water and initiate the development of a proposed national primary drinking water regulation. EPA received a number of comments in response to its preliminary regulatory determination for perchlorate(73 FR 60262, October 10, 2008) and the supplemental request for comment on the perchlorate regulatory determination (74 FR 41883, August 19, 2009) that were not directly related to the Agency's decision to regulate perchlorate in drinking water. These comments are compiled in response to comment code 7000 in this response to comment document. EPA is not directly addressing comments that do not relate to the Agency's decision on whether or not the Agency should promulgate a national primary drinking water regulation (NPDWR) for perchlorate under the Safe Drinking Water Act (SDWA). SDWA provides EPA with the authority to regulate public water systems through national primary drinking water regulations. Under this authority EPA plans to propose and promulgate a regulation that public water systems will have to comply with through monitoring and potentially using treatment techniques to reduce the levels of perchlorate in the drinking water they supply to their customers. The authority under SDWA does not apply to discharges, improper disposal or other releases of perchlorate or other contaminants. EPA therefore is not addressing comments related to these concerns under this action. EPA is also not addressing comments related to contaminants other than perchlorate or drinking water policies unrelated to the perchlorate regulatory determination.

EPA Comment Code: 7000

Comment: Further, there is an urgent requirement to safeguard public health through effective legal action requiring the provision of reliable tap water filters in all public establishments, inclusive of tax relief measures. All public schools, hospitals and restaurants should be equipped with this safeguard immediately to reduce the risk of further exposure.

Further, new programs must be established to ensure that private homes are able to afford installation of effective water filters.

Further, legal actions must be established to regulate and control the collection of appropriate disposal of such filters.

Sincerely,

Margaret Baco

EPA Comment Code: 7000

Comment: In closing we find it inexplicable that the Agency was able to interpret the statutory standard of what determines the "meaningful opportunity for health risk reduction" and make a determination in a relative short period of time. But, on the other hand, the Agency has not been able to interpret nor make a determination on similar statuary standards of "unreasonable risk to

health" (URTH) [42USC300g-5(a)(3)] or "protective of public" [42USC300g-1(b)(15)(B)]. What we find inexplicable is that the determination EPA has failed to make heretofore is more pressing to community water supplies than the determination EPA recently made for perchlorate. We believe that EPA should identify the URTH levels and what constitutes "protective of public health".

We thank you for the opportunity to provide comments regarding this important matter.

Sincerely,

Ed Thomas

EPA Comment ID: 20808
EPA Comment Code: 7000

Comment: As a new business in Michigan, we have taken the initiative to show concern for the environment in every way we can. We collectively look for ways to reduce our negative impact on the environment and search for ways to improve it. The Night Move started on the premise to get people out of their cars and into public transportation, reducing the air pollution from car exhaust. Also, we run our bus on biodiesel to reduce our emissions. For the emissions we do put out, we have partnered with CarbonFund.org to neutralize our carbon footprint. We don't stop there. Our flyers and advertisements are printed on recycled paper, passenger trash is recycled, and we reuse water to clean the bus. Of course, there are always ways to improve and we are always looking for them. We do this because we know what we do has an impact on the environment around us. This means we are impacting the people around us whether they use our services or not. We like to do our part to keep our environment clean and safe to live in, and we expect others to be just as courteous, especially our government.

Response: This is not a comment, a response is not necessary.

Stephen L. Johnson Administrator U.S. Environmental Protection Agency Washington DC 20460

Dear Administrator Johnson,

I am writing on behalf of Clean Water Action and it's 1.2 million members. Due to clerical errors, our organization's signature was not affixed to comments on the Agency's preliminary determination on perchlorate which were prepared and submitted by the Natural Resources Defense Council for the relevant docket. I want to draw your attention to our organization's support for these comments despite our signature not being on the official docket copy.

Response: The commenter's support for comments prepared by the Natural Resources Defense Council (comment letter ID EPA-HQ-OW-2008-0692-1988) is noted.

Commenter Name: Lenny Siegel
Commenter Organization: Center for Public Environmental Oversight
EPA Document ID: EPA-HQ-OW-2008-0692-2019
EPA Comment ID: 20855
EPA Comment Code: 7000

Comment: This reminds me of O.J. Simpson's criminal defense. He insisted that some third party or parties killed his wife and Ronald Goldman, but he showed little interest in finding the unknown perpetrators.

Response: No response necessary to the information provided by the commenter.

Commenter Name: Ron Curry
Commenter Organization: New Mexico Environment Department
EPA Document ID: EPA-HQ-OW-2008-0692-1796
EPA Comment ID: 20934
EPA Comment Code: 7000

Comment: In considering these comments, particularly this groundwater monitoring data, it is important for EPA to understand that New Mexico is very dependent on its groundwater resources for drinking water. New Mexico is an arid state, with relatively little surface water. New Mexicans obtain approximately 90 percent of their drinking water from groundwater aquifers.[FN11: Affidavit of William Olsen, Chief, Ground Water Quality Bureau, N.M. Environment Dep't, at 3, In re Appeal of Supplemental Discharge Permit for Closure (DP-1341) for Phelps Dodge Tyrone, Inc. (N.M. Water Quality Control Comm'n July 9, 2007) (Nos. WQCC 03-12(A) and WQCC 03-13(A)).] And New Mexico is growing and developing rapidly, placing greater demands on its aquifers. According to the New Mexico State Demographer at the University of New Mexico Bureau of Business and Economic Research, the population of New Mexico is expected to increase by 30 percent between 2005 and 2020, and by more than 50 percent between 2005 and 2035.[FN12: University of New Mexico, Bureau of Business and Economic Research, Population Projections for New Mexico and Counties, available at www.unm.edu/~bber. The information was confirmed in a telephone conversation with Adelamar N. Alcantera, Ph.D., New Mexico State Demographer, on November 24, 2008.] We therefore assume that much of the State's groundwater will be used for drinking water in the future. Consequently, there is a substantial likelihood that this perchlorate contamination will occur in public water systems in the foreseeable future.

Response: See response to comment code 7000.

Comment: RE: Docket ID No. EPA-HQ-OW-2008-0068

Comments on the US Environmental Protection Agencyâ€™s Preliminary Regulatory Determination on Perchlorate November 28th, 2008

Comment on the USEPA Office of Waterâ€™s Preliminary Regulatory Determination on Perchlorate.

Comment subjects

1. Relative Source Contribution (RSC) EPAâ€™s past RSC based on a "default" assumption versus EPAâ€™s RSC used in this Preliminary Regulatory Determination

2. The very particular case of perchlorate: Total effective equivalent perchlorate NOEL and RfD

3. Checking of some outcomes of this EPA preliminary determination with those obtained trough another road.

Response: This is not a comment, a response is not necessary.

Commenter Name: Jennifer Sass, PhD.

EPA Comment ID: 20996
EPA Comment Code: 7000

Comment: E. A final MCL below 1 ppb is both technologically and economically feasible.

Technical Feasibility

U.S. EPA's Method 314 approved ion chromatography detection protocol, for example, routinely detects perchlorate pollution at levels of 0.2ppb and the State of Massachusetts has established a 'reportable concentrations level for perchlorate of 2 ppb.[FN46: Thorne, Philip G. Field Screening Method for Perchlorate in Water and Soil, ERDC/CRREL Technical Report 04-8, 36 pp, Apr 2004.],[FN47: "Final Changes to the Massachusetts Contingency Plan -310 CMR 40.0000," downloaded from http://www.mass.gov/dep/cleanup/laws/perchlorate-310CMR40-07282006.pdf, November 2 2006.] Ion exchange technology is able to treat perchlorate contamination to levels considerably below 1 ppb. Treatment systems operating on perchlorate- impacted wells owned by Aquarion Water Company in Massachusetts, for example, treat wells to below 1 ppb.[FN48: "US Filter Recovery Services," downloaded from www.usfilter.com, November 2 2006.]

Economic Feasibility

The cost of complying with a perchlorate Maximum Contaminant Level of less than 1 ppb for the City of Rialto - one of the most impacted water systems in California - for example will be zero after cleanup costs are recovered from identified responsible parties. A complete economic feasibility study should also include an analysis of the costs associated with healthcare and lost work resulting from illnesses associated with perchlorate contaminated water.

Response: See response to comment code 6120. Feasibility and health risk reduction and cost analyses will be performed in support of a proposed National Primary Drinking Water standard.

EPA Document ID: EPA-HQ-OW-2008-0692-2082
EPA Comment ID: 21025
EPA Comment Code: 7000

Comment: Your letter also highlights states which have issued MCLs, including California, Massachusetts, and New Jersey (which has proposed, but not finalized a standard.)

As your letter points out, several states have issued standards or taken other regulatory steps relating to perchlorate in drinking water.. That is a separate issue from whether a national standard is advisable.

The Association of State Drinking Water Administrators noted in their recently filed comments that "States are generally in favor of EPA's decision not to regulate, but there are some states that do favor a national regulation on perchlorate, especially those who have already set their own standard."[FN7: Association of State Drinking Water Administrators, Letter to EPA Docket, Docket EPA-HQ-OW-2008-0692, Nov. 10, 2008.] The American Water Works Association, the largest organization of water supply professionals in the world, announced its agreement with EPA's preliminary determination, based upon the results of two independently commissioned assessments which support EPA decision. [FN8: American Water Works Association, Drinking Water: Preliminary Regulatory Determination on Perchlorate Docket EPA-HQ-OW-2008-0692; Nov. 10, 2008.]

Comment: Mr. Grumbles and Mr. Burneson, it is imperative that the USEPA, in Federal Register notices and in the Agency's Website, provide a facsimile number for the interested persons to submit written comments. I do not E-mail. I do not always have transportation to get to the post office. Foot problems keep me from walking long distances. Since I have a fax machine, I am able to submit comments not only to members of Congress, but State and Federal government elected officials, and agenices. All public comment submittal tools must be made available. The USEPA by doing otherwise limits the public's right to comment on issues.

Mr. Grumbles and Mr. Burneson, I notice that the USEPA provides an avenue to help the hearing impaired population participate. How does the USEPA help the visually impaired population participate in the public comment process?

Response: EPA acknowledges the commenter's request. In the future, written comments may be submitted to EPA's Docket Center Public Reading Room at the following fax number: 202-566-9744. Please include the appropriate Docket ID No. with your submission.

STATEMENT FOR THE RECORD

Subj: CLEAN WATER ACTION I CO DOCKET ID NO. EPA-HQ-OW-2008-0692

Dear Sir/Madame;

I wish it to be known that I support the testing, both routine and sustained, of water delivered by public, state or county for purposes of drinking, cooking, cleaning, bathing or their kind.

The Environmental Protection Agency operates as a public trust on behalf of the citizens of the United States. It is therefore both a custodial responsibility as well as a matter of good stewardship to perform all due diligence in the execution of the duties and responsibilities assigned to the EPA by the laws and directives of the United States. I wish you continued success as you carry out this mandate on behalf of your fellow citizens.

Kind regards, David L. Louden 7894 Bastille Pl Severn, MD 21144 410 551 7866 davidlouden@hotmail.com

Dear EPA Administrator Stephen Johnson

I write to your with an urgent request to regulate greenhouse gas emissions under the Clean Air Act.

Greenhouse gases are a serious threat to public health and people's welfare especially small children. The US must again take the lead on the issue at the Federal level.

The Supreme Court affirmed to EPA authority. I urge you to regulate by setting specific emission reduction standards for power plants, big factories, vehicles and fuels.

Please act John A Forbes III

To whom it may concern,

I fortunately live next to the Herald Harbor water tower in Crownsville, Maryland. Every year we get a report on the level of contaminants found in the drinking water supplied by this source. It would

be interesting to at least know the level of perchlorates in the water. I have no idea how to test for perchlorates or what level is safe or not. If they are harmful, it would be nice to know what levels they are in our water.

Thanks for your attention to this matter!

Thomas S. Soell 485 Mountain Rd Crownsville, MD 21032

Response: See response to comment code 6120. You may want to call your drinking water utility or state drinking water program to learn the results of past monitoring or to find out if monitoring is required in your state. If there is no requirement for monitoring in your state, you can have your water analyzed by a laboratory that is certified for the analysis of perchlorate or similar compounds. An EPA website provides a list of state certification officers or links to certified laboratories in your state.

Comment: This is really angering me, I may not be 18 yet and a legal adult, but i have as much right as any to drink UNCONTAMINATED water! this isnt the only problem too with drinking water! It has recently been recognized as of sept. 12th (today actually) in the new york times how all across the nation people can't even drink their tap water because there are contaminants from coal companies in them. The water has been found to contain barium, arsenic, lead, magenese, and other harmful chemicals. People get ugly and painful rashes just by letting it touch their skin and have to apply a special lotion after showing because it makes their skin BURN. A 6 year old boy was brought to the dentist and had to get metal caps on his teeth because the water had eaten away the enamel from his molars!

Government needs to address this because it is a fundamental living need- water. if we could ensure safely in our tap water, we could stop spending 10 billion dollars a year BOTTLING the stuff and just have people use a reusable safe stainless steel or hard safe-plastic bottle and save our ocean lots of pollution. Hey government! have uy heard there is a GIANT dump in the middle of the pacific ocean, circulating at a growing size that is already twice the size of Texas?!

Start addressing the things that really matter

Comment: In closing we find it inexplicable that the Agency was able to interpret the statutory standard of what determines the "meaningful opportunity for health risk reduction" and make a determination in a relative short period of time. But, on the other hand, the Agency has not been able to interpret nor make a determination on similar statuary standards of "unreasonable risk to health" (URTH) [42USC300g-5(a)(3)] or "protective of public" [42USC300g-1(b)(15)(B)]. What we find inexplicable is that the determination EPA has failed to make heretofore is more pressing to community water supplies than the determination EPA recently made for perchlorate. We believe that EPA should identify the URTH levels and what constitutes "protective of public health".

We thank you for the opportunity to provide comments regarding this important matter.

Sincerely,

Ed Thomas

Comment: To those in the EPA,

Why wouldn't you prevent this chemical from entering our waterways? How you could you think, that to some degree, this couldn't be harmful? Where are your standards? Frankly,would you want your own children exposed? Consider adopting a life of higher expectation; a life driven by the desire to do what is more difficult because IT IS THE RIGHT THING TO DO. The right thing to do hear is require perchlorate users responsible for the introduction into our water system to find a different way of disposing the chemical. Yes, that means money spent on research and development in order to create a manageable discarding mechanism. But is the alternative even thinkable: to expose our race to a chemical that could limit thyroid gland activity, ultimately leading to infant retardation, among a host of other unforeseen effects. I ask you to talk to your soul, deep down and see if it FEELS right to do what you are doing.

Kinldly , James Evangelos

EPA Comment Code: 7100 N/A May 2007 Comments

Response to Code 7100: Prior to publishing its preliminary regulatory determination for perchlorate (73 FR 60262, October 10, 2008) and its supplemental request for comment on the perchlorate regulatory determination (74 FR 41883, August 19, 2009), the Agency published a summary of the available information relevant to the perchlorate regulatory determination as part of its preliminary determination for 11 other contaminants on the second contaminant candidate list (72 FR 24016, May 1, 2007). EPA did not make a determination for perchlorate in the May, 2007 notice but rather described the available information relevant to the perchlorate regulatory determination and the steps the Agency planned to take to gather the information needed to make a regulatory determination. EPA received a number of comments related to perchlorate in response to this request. These comments are compiled in this section. See response to comment code 6120 for a discussion of EPA's decision to regulate perchlorate in drinking water. EPA's response to comments on the regulatory determinations for other contaminants under CCL 2 can be found at 73 FR 44251, July 30, 2008.

Comment: May 29, 2007 Water Docket US Environmental Protection Agency Mail Code 2822T 1200 Pennsylvania Avenue, NW Washington, DC 20460 DOCKET ID. NO: EPA-HQ-OW-2007-0068

Dear Assistant Administrator Grumbles:

The American Public Works Association (APWA) appreciates this opportunity to file comments on the proposed Regulatory Determinations Regarding Contaminants on the Seeond Drinking Water Contaminant Candidate List - Preliminary Determinations (72 FR 24016 (May 1, 2007)) and we agree with the decision announced in this notice. These comments were developed through input from APWA's Water Resources Management Committee.

APWA supports the Environmental Protection Agency's (EPA) efforts in making sound determinations as to whether or not a National Primary Drinking Water Regulation (NPDWR) should be developed for certain unregulated chemical contaminants under the Safe Drinking Water Act. The members of APWA's Resources Management Committee agree with the Agency's preliminary determination that a NPDWR is not appropriate for the eleven contaminants considered by EPA in this notice.

Response: No response is necessary to the information provided by the commenter. EPA's response to comments on the regulatory determinations for other contaminants under CCL 2 can be found at 73 FR 44251, July 30, 2008.

Re: May 1st Federal Register Notice for Preliminary Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant Candidate List (EPA-HQ-OW-2007-0068)

Dear Ms. Dougherty:

The Association of California Water Agencies (ACWA) would like to request an extension of the 60-day comment period on the May 1st Federal Register notice for the Preliminary Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant Candidate List.

Response: See response to comment ID 20264 under comment code 7100.

Commenter Name: Krista Clark
Commenter Organization: Association of California Water Agencies
EPA Document ID: EPA-HQ-OW-2007-0068-0157
EPA Comment ID: 20264
EPA Comment Code: 7100

Comment: Our request for an extension to 120 days is driven by the complexity of the issues, including perchlorate, and the large volume of supplementary information not included in the

Federal Register notice that must be considered before any comments, if necessary, are submitted to the Agency.

Response: After careful review and consideration of the comments EPA received on the May 2007 notice, the Agency made a final determination in July of 2008 that no regulatory action was appropriate for any of the 11 CCL 2 contaminants. However, EPA has provided 2 opportunities for further comment on the perchlorate regulatory determination (please refer to the following Federal Register Notices: 73 FR 60262, October 10, 2008 and 74 FR 41883, August 19, 2009).

Commenter Name: Krista Clark
Commenter Organization: Association of California Water Agencies

Comment: July 2, 2007 U.S. Environmental Protection Agency Office of Water Docket (Mailcode 2822T) 1200 Pennsylvania Ave. NW Washington, DC 20460

RE: Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant Candidate List-Preliminary Determinations Docket EPA-HQ- OW-2007-0068

Dear Docket:

The American Water Works Association appreciates the opportunity to comment on the preliminary regulatory determinations from the second Contaminant Candidate List (CCL2) as detailed in the May 1st Federal Register notice (72 FR 24016). AWWA is an international, nonprofit, scientific and educational society dedicated to the improvement of drinking water quality and supply. Founded in 1881, the Association is the largest organization of water supply professionals in the world. Our 60,000 plus members represent the full spectrum of the drinking water community: treatment plant operators and managers, environmental advocates, engineers, scientists, academicians, and others who hold a genuine interest in water supply and public health. Our membership includes more than

4,700 utilities that supply roughly 80 percent of the nation's drinking water. Based on this broad membership base, these comments should be considered as representative of the drinking water community in general. These comments are divided into two major sections, starting with general comments, and then followed by comments on specific contaminants discussed in the May 1st Federal Register notice.

General Comments

As previously mentioned, AWWA appreciates the opportunity to comment on the above referenced preliminary regulatory determinations. The Contaminant Candidate List (CCL) and subsequent regulatory determinations are the foundation for the standardsetting process resulting from the 1996 Safe Drinking Water Act (SDWA) Amendments. These two components are among the most important changes in EPA's approach for developing national drinking water regulations since the SDWA was initially passed in 1974. Ensuring that the appropriate contaminant is selected for regulation is the critical first step in the development of national drinking water regulation that should subsequently be followed by setting the standard at the appropriate level for that contaminant.

The May 1st Federal Register address the preliminary regulatory determinations from CCL2 and the CCL process and the subsequent regulatory determinations are intertwined. AWWA has significant concerns with the parallel ongoing process for the third Contaminant Candidate List (CCL3) and those concerns will be sent in a separate letter to Cynthia Dougherty upon submission of these comments.

Section 1412(b)(1)(A) of the 1996 SDWA Amendments details the criteria for identification of contaminants for potential regulation:

i. the contaminant may have an adverse effect on the health of persons; ii. the contaminant is known to occur or there is a substantial likelihood that the contaminant will occur in public water systems with a frequency and at levels of public health concern; and iii. in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems.

Another reform that is particularly applicable to this notice is found in Section 1412(b)(3)(A):

In carrying out this section, and, to the degree that an Agency action is based on science, the Administrator shall use -

(i) the best available, peer-reviewed science and supporting studies conducted in accordance with sound and objective scientific practices; and (ii) data collected by accepted methods or best available methods (if the reliability of the method and the nature of the decision justifies use of the data).

EPA's preliminary regulatory determinations for eleven contaminants on the second Contaminant Candidate List (CCL2) as published in the May 1st Federal Register complies with these two sections of the SDWA. AWWA commends EPA for not regulating contaminants purely for the sake of regulation, as was the case for some of the 83 contaminants listed in the 1986 SDWA Amendments. AWWA also commends EPA for using the best-available, peer-reviewed science in these preliminary determinations.

AWWA agrees with EPA's decision not to regulate these eleven contaminants. The occurrence levels are generally low based on national surveys such as the Unregulated Contaminant Monitoring Rule (UCMR), and regulation does not present an opportunity for significant risk reduction as mandated by the 1996 SDWA Amendments. These preliminary determinations follow the logic previously used in July 2003 for the first round of regulatory determinations and for the first six-year review (Roberson, 2005). AWWA believes that use of consistent logic in these two parallel regulatory efforts is important, contributing to a more transparent process, and commends EPA for proceeding in this manner. Based on the first round of regulatory determinations, a range of 0.02%-3.2% for national occurrence could be considered as the minimum threshold for development of a new regulation. National occurrence estimates for these eleven contaminants are well below this threshold, with boron having the highest prevalence of occurrence, at 1.7% of systems sampled in the National Inorganics and Radionuclides Survey (NIRS). Based on the first six-year review, a range of 0.53%-9.28% for national occurrence could be considered as the minimum threshold for revising an existing regulation.

Some might consider the lack of new contaminant regulations since the 1996 SDWA Amendments as an indication that this new regulatory development process is not working. AWWA disagrees with that viewpoint and believes, rather, that not regulating trivial contaminants is a positive development for EPA. Thirteen previously regulated contaminants had zero violations according to SDWIS data. Despite the lack of contaminant occurrence at levels of health concern, as inferred from the absence of violations for these contaminants, their regulation was nevertheless mandated by 1986 SDWA listing (Roberson, 2003).

A further indication that the new regulatory development process is working properly is the successful collection of occurrence data, through the Unregulated Contaminant Monitoring Rule (UCMR), to support regulatory determinations. Four of the contaminants (2,6-Dinitrotoluene, EPTC, Fonofos, Terbacil) in the current notice have zero occurrence based on the monitoring results from the first UCMR (UCRM1). These four contaminants were considered to be of potential concern based on the best information at the time back in 1998 when the first Contaminant Candidate List (CCL1) was published. UCMR1 monitoring results showed that these four contaminants were never detected in any of the more than 3,800 monitored systems.

AWWA recommends that EPA expand its discussion of the logic underlying the determinations for these eleven contaminants. The logic provided in the May 1st notice is not entirely clear. Generally, EPA needs to raise the level of transparency in its decision logic so that stakeholders can understand how data and information translate to determinations and to ensure consistency across the two parallel regulatory efforts (regulatory determinations and six-year review). For example, in the current notice there is no discussion about the remaining 40 CCL2 contaminants, what data are needed to make regulatory determinations, and what is being done to collect those data. Stakeholders have no way of knowing if more information on health effects or occurrence is required, or whether analytical methods research is needed before health effects and/or occurrence data can be reliably obtained.

The integration of EPA's overall drinking water research agenda with the overall regulatory development process is not sufficiently explained in this notice. The research being done on the balance of the contaminants from the second Contaminant Candidate List (CCL2) is not discussed. The process for conducting the appropriate research and then making the appropriate regulatory

decision for the 40 remaining contaminants needs to be clearly communicated to the drinking water community. For example, although national occurrence data from over 3,800 systems exists for acetochlor, molinate, and nitrobenzene, which were included in UCRM1 List 1, these three contaminants are not discussed at all in the May 1st Federal Register. It is unclear how the regulatory development process is driving EPA's research agenda.

AWWA recommends that, in the final notice, EPA develop a table on the information gaps for chemical contaminants similar to the table of pg. 24052 of the May 1st Federal Register for microbial contaminants. The limited research information in the current notice gives the appearance that little progress has been made since our 2002 comments on the first round of regulatory determinations. There is a strong need for appropriately communicating the body of research on CCL contaminants to the water sector.

AWWA wants to reiterate its concern that the 60-day comment period is not sufficient for adequately analyzing the complex issues surrounding perchlorate and for review, in general, of the associated background documentation. On May 22nd, AWWA requested an extension of the public comment period to 120 days and this extension was not granted. Not granting the requested extension is unfortunate, as the short comment period does not allow for adequate review by the drinking water community of the background documentation and for adequate debate on the complex policy issues. Perchlorate has been on EPA's regulatory agenda since its inclusion on the draft of the first CCL in 1997. While EPA has had over a decade to work through the complex policy issues surrounding perchlorate, the drinking water community had only 60 days to sift through these issues and make the appropriate policy decision.

Response: No response is necessary to the specific recommendations regarding transparency and information gaps as these comments were addressed in the July 2008 notice (73 FR 44255, July 30, 2008). Regarding the comment about perchlorate, please see response to comment ID 20264 under comment code 7100.

EPA Comment Code: 7100

Comment: Metolachlor

AWWA does not have any additional occurrence data on metolachlor or its degradates, but believes that more research is needed on the occurrence and health effects of many herbicides and pesticides and their degradates. The results of this research then need to be appropriately included in regulatory decisions by the Office of Pesticide Programs (OPP) and the Office of Groundwater and Drinking Water (OGWDW).

For example, metolachlor was not included in OPP's Cumulative Risk Assessment (CRA) for the chloroacetanilides because it was not apparent from currently available data that it shares the same target site in the nasal tissue as acetochlor, alachlor and butachlor, even though it does distribute to the nasal turbinates and "might" metabolize to quinoneimine, the active agent (as do acetochlor, alachlor and butachlor). Propachlor was also excluded from the Cumulative Risk Assessment for

similar reasons. EPA should promote further research to definitively determine whether or not metolachlor , a very widely used pesticide, is carcinogenic, as acetochlor, alachlor and metolachlor have very similar chemical structures.

The triazine herbicides are another example of the need to obtain the appropriate occurrence and health effects data of herbicides and pesticides and their degradates. AWWA has commented extensively in the past to OPP on the atrazine reregistration process. AWWA, through the Water Industry Technical Action Fund (WITAF) and a partnership with the Awwa Research Foundation (AwwaRF), has conducted extensive research on atrazine and its chlorinated metabolites. A listing of the published papers resulting from this research is enclosed as Appendix B.

The need for more occurrence and health effects data increases with the growing concern about potential reproductive and developmental effects from many herbicides and pesticides and their degradates. These new health endpoints will create monitoring and compliance challenges for water utilities, as the typical quarterly compliance monitoring is likely not appropriate for these new health endpoints. Both metolachlor and atrazine are on EPA's recently released draft list of 73 pesticides for Initial Tier 1 Screening as a potential endocrine disruptor under the Federal Food, Drug, and Cosmetic Act.

Methyl tertiary-butyl ether (MTBE)

AWWA supports EPA's decision not to make a regulatory determination for methyl tertiary-butyl ether (MTBE) at this time as the risk assessment is currently being revised. AWWA does not have any additional MTBE data to add to the topics listed in the May 1st Federal Register notice.

Microbial Contaminants

An information summary describing the state of the knowledge on the prevention, treatment, and health effects of cyanobacteria and its toxins would be useful for utilities and for state primacy agencies. The information should be concise and practical to ensure the document will be useful to water utility personnel. The summary should also include information on occurrence and conditions that might favor growth of algae and production of toxins. A strategy for communicating this information to utility customers should also be addressed. In addition to resources generated by EPA, the summary should include information of research funded by other organizations, particularly Awwa Research Foundation (AwwaRF).

Again, AWWA appreciates the opportunity to comment on these important drinking water issues. If you have any questions about these comments, please feel to call Alan Roberson or me in our Washington Office at 202-628-8303.

Yours Sincerely, Thomas W. Curtis Deputy Executive Director

RE: Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant Candidate List-Preliminary Determinations (Docket Number: EPA- HQ-OW-2007-0068)

To Whom It May Concern:

NRWA commends EPA for it's caution in withholding regulatory action on the 11 contaminants reviewed to date under the second contaminant candidate listing process (CCL2) and concurs with EPA recommendations in this regard. NRWA's position concerning these 11 contaminants, as well as the remaining candidates on the list, is influenced primarily by two recent papers that bear directly on the occurrence data and the risk evaluations that are an integral part of the CCL review.

RE: Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant Candidate List-Preliminary Determinations; Docket EPA-HQ-OW- 2007-0068

The Association of Metropolitan Water Agencies (AMWA) appreciates the opportunity to comment on the preliminary regulatory determinations for 11 contaminants as listed in the May 1, 2007 Federal Register (72 FR 24016). AMWA strongly supports the process required by the 1996 Amendments to the Safe Drinking Water Act (SDWA) that identifies potential contaminants, gathers needed information to determine if a national regulation is needed, and presents a formal evaluation and determination on whether or not to regulate a given contaminant.

Prior to the 1996 Amendments, Congress required regulation of specific contaminants based solely on the first step of the current process - the listing of potential contaminants. This lead to regulation of numerous contaminants that did not appear in drinking water at levels of public health concern

and wasted limited EPA and public resources. AMWA believes that this notice demonstrates that the 1996 process can work well in that the highest priority contaminants are selected for evaluation and that evaluation leads to informed decisions.

AMWA supports each of the 11 regulatory determinations made.

Comment: July 2, 2007 Comment Clerk Docket EPA-HQ-OW-2007-0068 Water Docket Environmental Protection Agency Mail Code: 2822T 1200 Pennsylvania Ave., NW. Washington, DC 2046 0

Dear Sir:

In response to the notice in the Federal Register of May 1, 2007 (Volume 72, Number 83) the Association of State Drinking Water Administrators (ASDWA) would is offering comments to the U.S. Environmental Protection Agency (EPA) on the Regulatory Determinations Regarding Contaminants on the Second Drinking Water Contaminant List -- Preliminary Determinations; Proposed Rule. ASDWA is the professional Association that represents the collective interests of the nation's state drinking water programs responsible for implementation of the Federal Safe Drinking Water Act.

Although some states have the expertise and resources to conduct their own evaluations of contaminant risk and may set their own, more stringent regulatory controls, most states rely on the EPA to determine which contaminants should be regulated in drinking water. It is critical that these determinations are based on sound science and accomplished through a transparent process with adequate input from all interested parties, especially the states. States expect EPA to follow the process prescribed in the Safe Drinking Water Act and we support the three statutory criteria for regulatory determinations:

(1) the contaminant may have an adverse effect on the health of persons;

(2) the contaminant is known to occur or there is substantial likelihood that the contaminant will occur in public water systems with a frequency and at levels of public health concern; and

(3) in the sole judgment of the Administrator, regulation of such contaminant presents a meaningful opportunity for health risk reduction for persons served by public water systems.

ASDWA appreciates the opportunity to provide the perspective of states on EPA's preliminary determination of which contaminants from the second Contaminant Candidate List (CCL2) should be regulated. States are generally in favor of the regulatory decisions that EPA is proposing in this notice but we do have a few comments to offer.

States generally agree there is no significant occurrence nor any "meaningful opportunity for health risk reduction" in regulating the 11 contaminants EPA has preliminarily decided not to regulate. One state indicated that dacthal and its degradates did appear in some drinking water system monitoring in their state but that it could be effectively managed in the absence of a federal regulation. Therefore, ASDWA supports EPA's decision not to regulate the 11 contaminants on the list in the May 1, 2007 proposal.

Response: See response to comment ID 20264 under comment code 7100.

Commenter Name: James Taft
Commenter Organization: Association of State Drinking Water Administrators (ASDWA)
EPA Document ID: EPA-HQ-OW-2007-0068-0169
EPA Comment ID: 20288
EPA Comment Code: 7100

Comment: Metolachlor and Methyl tertiary-butyl-ether (MTBE):

As stated in the Federal Register notice, EPA's primary need here is for additional contaminant occurrence data to support its regulatory decisions. Monitoring conducted by water systems under UCMRI and coming under UCMR2 will provide a solid base of occurrence data for future determinations. Many states have assisted EPA in implementing the UCMR monitoring to help assure that systems monitor and report as required. We believe these new data will add significantly to EPA's knowledge of the occurrence of contaminants on the Contaminant Candidate Lists and others considered for regulation.

Thank you for your consideration of these comments. Please contact me at 703-812-9507 or jtaft@asdwa.org if we can provide additional information or if any clarification of these comments is needed.

Sincerely, James D. Taft Executive Director

Response: See response to comment ID 20264 under comment code 7100.

Appendix 1 – Complete List of EPA Comment Codes

Comment Code	Comment Topics	Comment Code Used?
1000	General Comments	Y
1100	SDWA requirements and the CCL and Regulatory Determinations process	Y
1200	EPA's handling in the October 2008 FR Notice of perchlorate-related comments that were submitted following the May 2007 RegDet2 FR Notice	N
1300	Length of the comment period following the October 2008 FR Notice	Y

SUMMARY OF EXTERNAL PEER REVIEW COMMENTS AND DISPOSITION
for the 2008 external review draft of the report
Inhibition of the Sodium-Iodide Symporter by Perchlorate: An Evaluation of Lifestage Sensitivity Using Physiologically-based Pharmacokinetic (PBPK) Modeling

The draft report, *Inhibition of the Sodium-Iodide Symporter by Perchlorate: An Evaluation of Lifestage Sensitivity Using Physiologically-based Pharmacokinetic (PBPK) Modeling*, has undergone a formal external peer review performed by scientists in accordance with the U.S. EPA guidance on peer review (U.S. EPA, 2006). The external peer reviewers were tasked with providing written answers to general questions on the overall analysis and on parameter-specific questions in areas of scientific controversy or uncertainty. A summary of significant comments made by the external reviewers and the U.S. EPA's responses to these comments arranged by charge question follow. In many cases the comments of the individual reviewers have been synthesized and paraphrased.

The final external peer review report, including the charge to peer reviewers, (November 12, 2008) is available at http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=199347.

EXTERNAL PEER REVIEWER COMMENTS

The reviewers made several editorial suggestions to clarify specific portions of the text. These changes were incorporated in the document as appropriate and are not discussed further.

General Comments

Charge Question G1. ***Is EPA's analysis logical, clear and appropriate in depth and length? Has EPA accurately, clearly and objectively represented and synthesized the scientific evidence for the changes made to or specification of the model code and input parameters?***

Comment G1-a: All eight reviewers indicated that the U.S. EPA's analysis was logical, clear, and appropriate in length. Three reviewers explicitly indicated that the U.S. EPA provided an accurate, clear, and objective representation and synthesis of the scientific evidence for the changes made to or specification of the model code and input parameters. One reviewer recommended additional consideration and discussion of intra-human variability and quantitative and statistical approaches to address uncertainty.

> Response G1-a: In predicting perchlorate dosimetry and radioactive iodide uptake (RAIU) inhibition for the average individual in each lifestage, use of the model provides information for only a portion of the total human population variability. To characterize the full inter-individual variability within each lifestage would require specification of population distributions for each model parameter in each lifestage, including the distribution of sodium/iodide symporter (NIS) expression in each tissue where it occurs. Such data are not currently available. Further, the task of gathering all the requisite information, integrating it into a population parameter model (computer code), and

simulating the parameter distributions to estimate dose-response distributions is beyond the scope of the current effort.

Sweeney et al. (2003) is an example of using a physiologically-based pharmacokinetic (PBPK) model to evaluate overall population uncertainty, which is similar to what was suggested for perchlorate by the reviewer. Sweeney et al. (2003) performed an analysis for acrylonitrile (AN), where estimates of parameter variability were combined with model-prediction sensitivity coefficients (for each parameter) to estimate overall population uncertainty. Considering internal dose metrics of peak or average blood concentrations of AN or the key oxidative metabolite, cyanoethylene oxide, the ratio of exposure metric in the 99^{th} percentile of the population to the average individual was found to be no greater than 2.2. This is similar to the default inter-individual uncertainty factor for toxicokinetics of 3.

While the Sweeney et al. (2003) result is a single analysis, for a metabolized VOC, the intrinsic variability in human physiology incorporated by Sweeney et al. would be the same for perchlorate. However, to fully account for variability in the perchlorate analysis, one would also need to consider several additional factors across and within lifestages, such as variability in NIS levels and urinary clearance.

Comment G1-b: One reviewer noted that the draft report states that calculations were made for "subgroups, including potentially sensitive subgroups" although population-based modeling (with considerations of inter-individual and intra-individual variability) was not performed.

Response G1-b: A paragraph was added at the end of the introduction (Section 1) to clarify that the model predictions provided what could be considered central tendencies for specific subgroups.

Comment G1-c: One reviewer recommended considering the extent to which the gestation week 40 fetus may or may not represent the first and second trimester fetus.

Response G1-c: Text was added to the document (Section 4.2) to describe the rationale for using the model to predict %RAIU inhibition for only the gestation week (GW) 40 fetus. Briefly, the GW 40 fetus is not intended to represent the first or second trimester fetus. Key fetal parameters are too uncertain for quantitative application of the model to earlier GWs. There are no data to support model predictions of %RAIU inhibition in the fetus at the earlier GWs.

Comment G1-d: One reviewer asked for an expanded discussion of the motivation for some of the statistical fits to the data.

Response G1-d: Text was added to the beginning of Section 3 to provide a discussion and motivation for the methods used to estimate model parameters.

In short, the U.S. EPA's approach was to generate algebraic functions, through curve-fitting, that would provide good approximations of time- or BW-dependent changes in parameter behavior, using a relatively small number of parameters and simple

analytic tools (curve-fitting in Microsoft Excel) that could be readily applied. We believe that differences in the quantitative PBPK model predictions between using these curve-fits and what one might obtain by more extensive analyses would be small.

Charge Question G2. ***Please identify any additional studies or other data sources that should be considered in the assessment of the specific parameters addressed below, including urinary clearance (of iodide and/or perchlorate) and ingestion rates (breast milk, formula and water), especially in neonates.***

Comment G2-a: Five reviewers identified additional studies for the U.S. EPA to consider. One reviewer recommended that the U.S. EPA seek additional data to re-affirm the water ingestion rates, "particularly the use of the 90th percentile values in which the situations exceed the expectation of the fundamental knowledge." However, this reviewer was not aware of any studies or data sources that the U.S. EPA could use. One reviewer suggested that additional data collection could be done in the future, but noted that the U.S. EPA's use of DeWoskin and Thompson's data for scaling renal excretion for infants by body weight and extrapolating to a 60-day-old, 5 kg child is reasonable. One reviewer could not identify the reference Gentry et al. 2001 and suggested an alternative data source (Dewey et al., 1991) for the residual milk volume parameter.

Response G2-a: The Agency evaluated Dewey et al. (1991) and agrees that this reference provided a value (0.109 L) for residual milk volume that may be appropriate for use in the Clewell et al. (2007) model. Gentry et al. (2001) was referenced in the model code by the model authors for the original value used in the model (VMk = 0.632 L), but not in the corresponding manuscript and a Gentry et al. (2001) reference with this value could not be located. The value for residual milk volume (VMk) was changed from 0.632 to 0.109 L. Model sensitivity to VMk was tested and an 83% decrease from 0.632 to 0.109 L for VMk resulted in less than 3% change in model calculated percent inhibition of radioiodide uptake. Thus, the model is not sensitive to this parameter. This revision is documented in Appendix A, Section A.3, and an example of the impact of this change on model predictions is shown in A.7.

Comment G2-b: One reviewer recommended including a compartment analysis figure for the current model used by the U.S. EPA.

Response G2-b: Figures of the PBPK model structures, as they appeared in Merrill et al. (2005) and Clewell et al. (2007) for perchlorate and radioiodide were added to the report as Figures 1-1 and 1-2. Modifications to the model code did not alter the primary model structure shown in these figures, as originally published. However, the blood flow rates have been corrected to be blood plasma flow rates, rather than total blood flow rates, as described in detail in Appendix A, Section A.5.

Charge Question G3. ***Besides the specific parameters identified below, please comment on any other parameter or model choices described in the document that you think are incorrect or require further explanation or where other available information could provide better estimates.***

Comment G3-a: Two reviewers agreed with the U.S. EPA's parameter and model choices; one noted that the parameter values used by the U.S. EPA are supported by the literature. One reviewer stated that the methods used for scaling of clearance to body weight, age and surface area are appropriate; however, such scaling is most accurate when the substance is not reabsorbed or secreted. This reviewer recommended that the U.S. EPA consider alterations in NIS expression (Faggino et al., 2004) and whether other formulas could be used to more accurately reflect GFR in children and suggested two references (Check et al., 1977; Schrier, 2001). One reviewer declined to comment.

Response G3-a: The PBPK models were originally developed to simply describe the alterations in NIS expression for different lifestages. A change in NIS expression is assumed to be described by a change in the NIS maximum velocity (Vmax) which is scaled by $BW^{0.75}$. Using allometric scaling of Vmax, there is greater activity per tissue volume at a lower BW. Faggino et al. (2004) describes the use of immunohistochemistry to compare NIS (and Pendrin) expression in children less than 12 years to children greater than 12 years, and shows a higher percentage of stained cells in younger children (with intensity of staining ~ constant across age). In fact, this is what one expects/predicts from allometric scaling as currently used in the model: higher activity/tissue volume with lower BW. However, histochemistry only provides qualitative information. Also, because Faggino et al. (2004) only reported data for children in two categories (less than or greater than 12 years), the published results could not be used to evaluate the appropriate shape for an age-dependent function. The NIS expression data in Faggino et al. (2004) are not sufficiently detailed (vs. age or BW) to quantitatively inform the age-dependence of NIS.

The Agency also evaluated Cheek et al. (1977) for information to describe GFR in children. Cheek et al. (1977) indicates that creatinine serves as an indicator of tissue mass, and specifically, clearance would scale with muscle mass. The current PBPK model calculates muscle mass, as a constant fraction of body weight (BW). Therefore, to simply replace BW with muscle mass as the explanatory variable on which scaling is based would simply result in a change in the multiplicative constants with no change in the model predictions. Cheek et al. (1977) also states that intracellular water (ICW) correlates linearly with muscle mass, provides data on individual age, BW and ICW, and points to an earlier reference demonstrating that relationship. If the relationship is direct proportionality, then the results in Cheek et al. (1977) for ICW could be used directly to correlate muscle mass with age—age being the independent variable in the PBPK model. Otherwise (i.e., if the relationship includes a non-zero constant term), these data would need to be combined with those of the earlier paper to obtain the correct relationship for muscle mass vs. age, and clearance could be varied in proportion to muscle mass changes with age.

The general trend indicated – muscle mass increasing as a fraction of BW with age – means that scaling urinary clearance in proportion to muscle mass would lead to a prediction of *lower* clearance per unit BW in children of all ages, which would increase

the predicted dose-response (risk) relative to the current model application. The magnitude of this change cannot be determined without a complete data analysis but is likely to be most significant in younger children, where the difference in percent muscle mass is greatest. In addition, Clewell et al. (2002, Crit. Rev. Toxicol., 32:329-389), citing a physiology textbook, show a table with skeletal muscle increasing from 25% of BW in neonates to 40% in adults, which indicates that scaling urinary clearance with muscle mass would give results qualitatively in agreement with the current ones, though with a more mechanistic basis.

The reviewer also provided a reference on scaling clearance with creatinine levels, but use of such a formula would require a relationship between age or BW and creatinine levels. The pages in the Schrier (2001) reference noted by the reviewer are in a chapter by Clark and Chantler and describe the correlation of GFR with height and creatinine. Since Cheek et al. (1977) indicates that creatinine is an index for muscle mass, such an approach would likely lead to the same results as directly correlating clearance with muscle mass or ICW. So, there does not appear to be additional value in also evaluating an explicit correlation with creatinine levels. Therefore, while the U.S. EPA does not dispute the suggestion that scaling clearance with muscle mass is preferable in general, no such change has been made since the data or specific, quantitative information that would lead to substantive changes in model predictions for perchlorate and iodide are not available.

Comment G3-b: One of the reviewers stated the value used for the residual milk volume seemed unrealistically high and provided information and references for consideration. This reviewer recommended that the U.S. EPA conduct a sensitivity analysis to decide if and how this issue should be addressed.

Response G3-b: See response to comment G2-a. The residual milk volume parameter (VMk) was further evaluated by the U.S. EPA. VMk was changed from 0.632 to 0.109 L based on data from Dewey et al. (1991), as suggested by the reviewer, and is discussed in detail in Appendix A, Section A.3.

Comment G3-c: One reviewer noted that focused data collection might facilitate the improvement of the partition coefficient (PC) values used in the model as well as the urinary clearance values for perchlorate and iodide.

Response G3-c: Considering variation in PC values between species is usually modest, it is unlikely that age-dependent changes within a species (humans) will be large enough to substantially alter model predictions. The U.S. EPA agrees that additional data on the variation in perchlorate and iodide urinary clearance among humans would be valuable.

Comment G3-d: One reviewer requested that the rationale for using the 90^{th} percentile value be provided in the report. The reviewer noted that this value seems to be used as an upper bound limit, although the U.S. EPA states in the document that this is not the case.

Response G3-d: Additional rationale for using the 90th percentile value was added to Section 3.3 and 4.3. While the 90th percentile water ingestion rate characterizes a high-end drinking water exposure, the model prediction is not considered to be an 'upper-bound' because of the use of mean or average lifestage parameter values.

Comment G3-e: One reviewer stated that the U.S. EPA's analysis partially addressed biological susceptibility and coexposures; however, the Agency needs to consider additional susceptible subgroups (i.e., those with clinical and subclinical hypothyroidism, the genetically predisposed, and those that are iodine deficient) and the coexposures with thiocyanate and nitrate.

Response G3-e: The U.S. EPA's Office of Research and Development (ORD) was tasked with evaluating the effects of perchlorate on radioiodide uptake in different human lifestages using the Clewell et al. (2007) and Merrill et al. (2005) PBPK models and as noted by the reviewer, the U.S. EPA has accounted for perchlorate coexposure through both food and drinking water. Evaluating the impact of coexposure to other iodide uptake inhibitors (e.g. thiocyanate or nitrate) was not within the scope of this analysis.

Additionally, terms to account for co-exposures to thiocyanate and nitrate would have to be added to the models developed by Clewell, Merrill, and colleagues, and appropriately parameterized to represent their interactions with NIS. At a minimum such terms would have to include estimates of internal concentrations of these compounds and binding or inhibition constants for their interactions with NIS. This degree of model revision is beyond the scope of the current effort, and the data necessary to set the requisite model parameters may not even be available.

Likewise the models have not been specifically parameterized to describe hypothyroid or iodine deficient individuals. While the figure provided by the reviewer may in some ways be qualitatively correct, accounting for the impact of iodide deficiency would require a knowledge of the degree to which NIS levels change in the deficient person and also would require an understanding of the significance or impact of a change in iodide uptake. The current knowledge of thyroid function is insufficient to predict the impact of such incremental changes. Additionally, there are many factors (e.g. production and metabolism of thyroid hormones) that could affect iodide kinetics in a hypothyroid state, thus adjusting the PBPK models to accurately predict effects in hypothyroid/iodine deficient individuals would likely require an extensive amount of additional data collection, research and model development beyond the scope of this analysis.

The U.S. EPA's rationale for not evaluating these subgroups was added to the document in Section 5.1.

Comment G3-f: One reviewer identified a need to develop and thoroughly test a consistent framework for modeling [urinary clearance] processes for different lifestages. The reviewer stated that correcting the inconsistencies, identified in Appendix B of the document, would be a first step towards implementing such a framework.

Response G3-f: A more detailed response is provided under comment A1-e below (section on urinary clearance). The primary inconsistency identified by the U.S. EPA

was that urinary clearance of iodide and perchlorate were varied independently, sometimes quite differently, when the mechanism by which they are cleared is presumed to be the same. Based on that assumed common mechanism, the U.S. EPA concluded that when iodide clearance is decreased by 60%, for example, perchlorate clearance should also be reduced by 60%. The changes in the model implemented by the U.S. EPA corrected all such inconsistencies.

The significant physiological changes occurring in the mother at childbirth could result in a significant change in clearance between pregnancy and the postpartum period, so no further "consistency" in treatment of clearance across lifestages was assumed.

Charge Question G4. ***Please discuss research that you think would be likely to increase confidence in these models and their use in predicting RAIU inhibition by perchlorate in different life stages (for an average individual within each life-stage).***

Comment G4-a: Three reviewers provided recommendations for future research including assessing the effect of perchlorate on the clearance of NIS substrates, studying the mechanisms of perchlorate inhibition of NIS, investigating the toxicity of NIS substrates in the presence and absence of perchlorate, estimating urinary clearances of environmental pollutants in infants and neonates, biomonitoring of perchlorate, iodide, thiocyanate and thyroid hormone during and after pregnancy and during lactation in smoking and no-smoking women, measuring perchlorate in non-composited baby formula samples, and studying renal clearance of iodine and perchlorate during pregnancy and postpartum.

Response G4-a: The U.S. EPA agrees that additional information would be valuable to future revisions of the PBPK models.

Comment G4-b: Two reviewers recommended that the Agency consider additional methods. One suggested a probabilistic sensitivity/uncertainty analysis and eventually the feasibility of population-based PBPK modeling. The other reviewer asked the U.S. EPA to consider the possibility of simulating iodine-deficiency (or hypothyroidism) in pregnant women.

Response G4-b: The U.S. EPA recognizes that a powerful aspect of PBPK models is that they provide an excellent framework for parameterizing and simulating the effects of population distributions in physiological, biochemical, and metabolic parameters; however, this is outside the scope of the current analysis.

The reasons why the models were not extended to describe hypothyroid or iodine deficient individuals were outlined above in G3-e.

Comment G4-c: One reviewer noted that if model output is sensitive to the residual milk volume parameter (see questions G2 and G3), confidence in the modeling could be increased by a better description of this parameter. Another reviewer stated that using real-world data like those from Blount et al. (2006) with the model would increase confidence, but acknowledged that the Blount et al. study does not include children ages 6 and younger. Another reviewer recommended evaluating newer estimates of renal function by Schwartz.

Response G4-c: The PBPK model output for the lactating woman and breast-fed neonates were not sensitive to the residual milk volume parameter (VMk) value; however, the parameter value was changed to reflect the data in Dewey et al. (1991) (as explained in responses G2-a and G3-b and discussed in detail in Appendix A, Section A.3.).

Blount et al. (2006) provide data relating urinary levels of perchlorate to changes in T4 and TSH. Since the model does not predict T4 and TSH, these results could only be used qualitatively; i.e., if the urinary levels are converted to exposure rates, then the RAIU changes predicted over that range may be similarly significant. This would not provide significant support for the current analysis and was not explored further.

A paper for which Schwartz was the first author was not located; however, a recent publication by Work and Schwartz (2008) describes a clinical approach for measuring GFR in children, but it does not provide data that could be used to estimate values of GFR in children of different ages or BWs.

Comment G4-d: One reviewer recommended that the U.S. EPA state that the modeling effort is theoretical because it has not been validated; however, this reviewer suggested using existing data to help test the model predictions and validate the model. The reviewer noted that the U.S. EPA's report did not include information about concentrations of perchlorate and iodine in milk as a function of perchlorate dose and suggested reviewing Pearce et al. (2007) which provided the relevant information. The reviewer noted that without this information it is impossible to determine whether the U.S. EPA's results are consistent with the literature showing no correlation between perchlorate and iodine in breast milk samples.

Response G4-d: The model does predict inhibition of radioiodide transfer into breast milk, although those specific predictions were not included in the report. Pearce et al. (2007) showed no significant reduction (trend) in breast-milk iodide with perchlorate exposure, which is qualitatively in agreement with model-predictions, where inhibition of transfer to breast milk was found to be no more than a few percent – low enough to be insignificant relative the amount of variability in breast-milk iodide. The U.S. EPA plotted model predictions against the data of Pearce et al. (2007) to more clearly demonstrate the level of agreement between the two sets of results. This is now described in section 4.1.1.2 and shown in Figure 4-2 of the document.

Comment G4-e: One reviewer noted that the models use arterial plasma concentration and whole blood flow rates and recommends either the influx in all mass balance equations should correspond to whole blood concentrations or the flow rate should correspond to plasma flows. The reviewer suggested evaluating the assumption to see whether this change would have any consequence.

Response G4-e: As the reviewer suggested, plasma flow, instead of blood flow, should have been used to describe delivery of perchlorate and radioiodide to the tissues in conjunction with the concentration of perchlorate or radioiodide in the plasma. Cardiac output (total blood flow) was adjusted to reflect plasma flow by multiplying by the plasma:whole blood volume ratio (PBratio=Volume_of_Plasma / Volume_of_Blood =

~0.557), thereby decreasing the flow to the tissues. This had a minimal impact on model output within the experimental error for the average adult (at 7 μg/kg-day changed from 2.1% RAIU inhibition to 1.6%); however, the use of plasma flow was retained to increase physiological accuracy of the model. A description of this change was added to Appendix A, Section A.5.

Charge Question G5. ***Does EPA accurately characterize the strengths and limitations of the analysis? Please comment on any particular strengths that may not be mentioned or adequately characterized for the estimates of RAIU for different life stages. Please also comment on any specific sources of uncertainty that you believe have been overlooked in EPA's analysis or that require further discussion, and which might be significant to EPA's estimates of RAIU for different life stages.***

Comment G5-a: Four reviewers indicated that the U.S. EPA adequately characterized the strengths and limitations. One of these reviewers suggested that the U.S. EPA's modeling analysis could be improved by including comparisons of the model simulations to experimental data. Another reviewer agreed that the strengths and weaknesses of the analysis were adequately highlighted but noted that the limitations associated with the lack of validation were not addressed.

Response G5-a: Section 4.1.1 was added to include several comparisons of model predictions with published data.

Comment G5-b: Two reviewers did not specifically address whether the characterization of strengths and weaknesses was adequate. One reviewer identified the explicit listing of unresolved issues and inconsistencies in the modeling as the main strength of the analysis and description in the document. This reviewer listed the main limitations as the use of point estimates rather than a distributional approach to characterize exposures, the emphasis on "average" individuals rather than populations, and the lack of consideration of NIS inhibitors other than iodide and perchlorate. The other reviewer considered use of the PBPK model to assess life-stage sensitivity, use of the fetus to evaluate relative sensitivity, and consideration of relevant route/source of exposure as strengths of the analysis, whereas the exclusion of certain subgroups (e.g., the elderly, early gestation fetuses, iodine-deficient or hypothyroid pregnant women) and not considering parameter value variability within subgroups were weaknesses.

Response G5-b: The reviewers note observations about the limitations and weaknesses in the analysis of lifestage relative sensitivity of percent inhibition of thyroid radioiodide uptake using the Clewell et al. (2007) and Merrill et al. (2005) PBPK models. These observations and suggestions by the reviewers would provide for a strong population analysis, coexposure analysis, or analysis of other potentially sensitive subgroups (e.g. elderly, early gestation fetuses, iodine-deficient, or hypothyroid individuals). Incorporating these suggestions into the analysis would expand the scope of the lifestage comparison, but would not directly strengthen the current approach examining "average" individuals in the subgroups. Additional work beyond the scope of the current exercise and data collection would be necessary to improve upon the weaknesses mentioned by

the reviewers. For example, to accurately predict effects of perchlorate in populations exposed to other iodide uptake inhibitors would require additional PBPK models for the compounds of interest and additional data on the potential variability of parameters across populations would need to be obtained. Currently, urinary clearance is the only parameter for which we had sufficient data to test model sensitivity to several biological plausible values.

Comment G5-c: One reviewer recommended conducting an uncertainty analysis to look at the implications of using direct IV dose of radioiodide (rather than oral ingestion) for bottle-fed infants to determine iodide uptake inhibition.

Response G5-c: The models as developed by the authors were not intended to simulate the effect or to estimate the impact of perchlorate on inhibition of dietary iodide uptake, nor are the models capable of describing the large mass flux of dietary iodide. Additionally, the model developers (Clewell and Merrill) primarily used IV doses of radioiodide because the data in literature available on perchlorate's effect on thyroidal iodide uptake was predominantly from radioiodide given as an IV dose. This was maintained for all lifestages (except breast-fed infant) in this analysis to provide for determination of relative lifestage sensitivity. The Agency did not simulate an IV dose of radioiodide to the breast-fed infant, but rather accounted for the diminished amount of iodide the infant would receive through breast milk. This approach was used to also reflects a decrease in the external dose of iodide that a breast-fed infant would receive. For all other lifestages, perchlorate is assumed not to reduce the external dose of iodide.

Comment G5-d: One reviewer recommended additional discussion of the limitations of focusing on "healthy" individuals and of not considering large susceptible populations, and adding a scenario analyses to ascertain inhibition levels for plausible cases of higher susceptibility.

Response G5-d: A discussion of why the U.S. EPA focused on "average" or "healthy" individuals was added to Sections 5.1 and 5.2. Data are lacking to derive model parameters and validate model predictions of radioiodide uptake inhibition for individuals that may potentially be more susceptible. See response to G3-e for more detail regarding susceptible subpopulations.

Charge Question G6. ***As recommended in EPA's 2000 Risk Characterization Handbook, is the analysis transparent in terms of the steps, logic, key assumptions, limitations, and decisions? Specifically, does characterization of the results of EPA's work fully explain: a) the analysis approach employed; b) the use of assumptions and their impact on the analysis; c) the use of extrapolations and their impact on the analysis; d) plausible alternatives and the choices made among those alternatives; e) the impacts of one choice vs. another on the analysis; f) significant data gaps and their implications for the analysis; g) the scientific conclusions identified separately from default assumptions and policy decisions, if any; and h) the major conclusions, and the discussions of EPA's confidence and uncertainties in the conclusions?***

Comment G6-a: All reviewers agreed the analysis complied with the Risk Characterization Handbook and was transparent. Two reviewers recommended adding a separate section with a summary of the limitations and uncertainties, one of these reviewers also recommended adding lists of the data gaps and of the major perceived weaknesses. One reviewer recommended clearly listing plausible alternatives for some of the parameters and how these alternatives will affect the model.

> Response G6-a: A separate section (5.2) was added to the document that specifically addressed the limitations and uncertainties of the PBPK modeling. Alternatives and effects on model output for urinary clearance parameter estimates were listed in Table 4-2 of the document. No other alternatives were tested due to lack of information for possible alternatives.

Comment G6-b: One reviewer questioned the availability of additional data in the literature that could be used to further validate the model.

> Response G6-b: The U.S. EPA agrees that the existing data provide only limited potential for validation and additional data would be beneficial.

Comment G6-c: One reviewer stated that some of the justifications in the document are weak, especially with respect to inconsistencies in modeling urinary clearance processes. The reviewer acknowledged that correcting the inconsistencies may not substantively affect the calculated outcomes but a fully defensible model should incorporate up-to-date scientific information and assumptions that are consistent across lifestages.

> Response G6-c: As stated in responses above, the U.S. EPA identified and corrected inconsistencies in the treatment of urinary clearance, where possible. The U.S. EPA determined that the current approach is appropriately consistent with the assumed mechanisms and known differences in urinary clearance of perchlorate and iodide, and generally known changes in renal function across ages and lifestages.

Comment G6-d: One reviewer suggested clarifying why the elderly and teens were not included in the subgroups and why the results of the analysis are also applicable to chronic exposure situations. This reviewer recommended the U.S. EPA provide justification for the choice of 24-hr RAIU, and not 24-hr AUC (area under the plasma concentration versus time curve), as the endpoint and further discuss the sensitivity of key input parameters as a function of age to the use of a single RAIU value in infants and adults.

> Response G6-d: The NRC (2005) noted that fetuses, infants, and developing children are the most sensitive lifestages. When exposure from food and water is considered, infants and young children receive relatively higher doses than adults and fetuses. Thus, EPA chose to focus on these groups, as well pregnant and lactating women. Available data do not indicate that the elderly and teens are relatively more sensitive or highly exposed when compared with other lifestages. The results of this PBPK analysis are applicable to

chronic exposure situations because the perchlorate pharmacokinetics are such that steady-state is reached within a few days to a week. Longer-term changes in physiological variables associated with aging will result in changes in perchlorate pharmacokinetics, but those longer-term changed are largely bracketed by the specific ages and situations considered in this analysis. The National Academy of Sciences (NRC, 2005) concluded that if the perchlorate exposure is sufficiently low that the acute effect of RAIU inhibition is kept safely below the identified NOEL, then the risk of chronic exposure to perchlorate will be minimal. The U.S. EPA considers it unlikely that, at the levels of inhibition which occur at the RfD, there will be a cumulative long-term effect.

Justification for using 24-hr RAIU inhibition as the dose metric was added to the introduction (Section 1). Briefly, the series of PBPK models developed by Merrill and Clewell used RAIU inhibition as the primary dose metric. 24-hr RAIU inhibition was the dose metric chosen by EPA as opposed to a 24-hr AUC of perchlorate because the amount of RAIU inhibition was defined as a precursor to a critical effect and as the point of departure for the derivation of the RfD.

Comment G6-e: One reviewer recommended additional discussion on the forms for statistical fits, the use of 90th percentile versus mean values for parameters, the failure to address certain large susceptible populations, and the use of the GW 40 fetus. This reviewer requested more quantitative and rigorous treatment of uncertainty.

Response G6-e: Use of GW 40 fetus was described in G1-c response and text was added to the document in Section 4.2. The rationale for the use of 90th percentile for water ingestion was detailed in responses (G3-d, B1-d, C1-e, and C2-d) and additional rationale was added to Section 4.3 of the document. A discussion of other susceptible subgroups and the challenges in using the current PBPK models to evaluate these subgroups was added to Section 5.1 of the document.

Parameter-Specific Charge Questions

A. Urinary Clearance

Parameter-Specific Charge Question A1: ***Please comment on the appropriateness of the input values selected for maternal urinary clearance during pregnancy and lactation in EPA's analysis. Are the available data and rationale for the values selected transparently and objectively described? Are you aware of other publications or data that could be used to guide these choices or which provide alternative input values that are equally valid or more appropriate? Likewise, are the values selected for urinary clearance for the infant and older child the best estimates, given the available science and data? Are there other data that would provide better (or equally valid alternative) guidance or estimates? Is there any reason to believe that urinary clearance might not be a limiting factor in the elimination of perchlorate for infants?***

Comment A1-a: Regarding maternal urinary clearance, seven reviewers agreed that the input values were appropriate. The other reviewer disagreed with the rationale for the maternal

urinary clearance values but agreed with the value used for the lactating mother. This reviewer asserted that the available human data, which shows no measurable or consistent difference in urinary clearance between pregnant and non-pregnant women, should be used.

Response A1-a: The discussion of urinary clearance in the primary document has been expanded (Section 3.1) to more fully explain the U.S. EPA's rationale for selecting the urinary clearance rates used. Information is limited to derive maternal (during pregnancy and lactation) and infant clearance values; thus given the available information, the U.S. EPA believes the values used to be both appropriate for sensitive individuals and within the range of biological realism.

The available data and information are inconsistent and not clear to determine urinary clearance of perchlorate and iodide during pregnancy. General information on the clearance of metabolized compounds is considered a weak indicator for potential changes in iodide and perchlorate clearance because different mechanisms are involved.

Also, since clearance is the ratio of the urinary excretion rate to blood concentration, it is entirely possible for excretion to remain approximately constant, or even increase, while clearance is decreased. On average, excretion of iodide must equal its ingestion rate, independent of how clearance may vary. So, data in humans which show little or no changes in the clearance of other compounds, or little or no changes in iodide *excretion,* may still be consistent with a decrease in the urinary clearance of iodide and perchlorate. The PBPK modeling in rats, however, showed a decrease in the clearance of both perchlorate and iodide (both decreasing approximately the same amount).

Finally, while Aboul-Khair et al. (1964) measured iodide clearance directly, the methods used to measure blood iodide levels at that time were not the methods used to generate the more recent data available for rats. Thus the evidence for each of the three urinary clearance rate possibilities has both strengths and weaknesses, and the U.S. EPA concluded that none of the three was clearly superior. The U.S. EPA is not aware of newer data for urinary clearance of iodide or another entity with a similar clearance mechanism (e.g., bromate) that it could have used for pregnancy in humans.

Comment A1-b: Five reviewers specifically noted that the data and rationale were transparently and objectively described. One reviewer stated that the clearance rate choices for the mother during pregnancy and lactation were arbitrary and the rationale was not provided. One reviewer suggested the U.S. EPA improve the discussion of maternal urinary clearance values, and one reviewer also questioned the curve fit and data shown in Figure B-6.

Response A1-b: Additional explanation of the rationale for U.S. EPA's choice of maternal urinary clearance values has been added to Section 3.1. A general statement on the approach used for curve fitting was added to Section 3 (see response to comment G1-d) to address the reviewer's comment about Figure B-6.

Clewell et al. (2007) had estimated reduced urinary clearance of perchlorate during lactation (based on lactational rat:average adult differences) but assumed that iodide clearance was unchanged from the average adult. The U.S. EPA considers this option to be inconsistent, since changes in renal function that reduce perchlorate clearance are likely to have a similar effect on iodide clearance. Therefore this option

was not considered a plausible alternative for use during lactation. Further, the male rat PBPK model (Merrill et al., 2003) used urinary clearance rate (CLUC) values of 0.07 and 0.05 L/hr/kg$^{0.75}$, respectively, with virtually identical values in lactating rats (0.07 and 0.06 L/hr/kg$^{0.75}$, respectively; Clewell et al., 2003). Thus, the application of a "parallelogram" approach to extrapolate the rat results to humans indicates that clearance during human lactation should be the same as for the average adult (male) human, rather than having *both* perchlorate and iodide clearance reduced from the average adult, as was indicated during pregnancy. Therefore, the existing data support only two options for perchlorate and iodide clearance during lactation: increased clearance relative to the average adult, based on the results of Aboul-Khair et al. (1964) and equal clearance relative to the average adult, based on the PBPK modeling in rats. The U.S. EPA considers the two alternatives to have equivalent likelihood. Given this uncertainty, the U.S. EPA then chose the lower clearance (more sensitive) option: clearance equal to that of the average adult. Alternatives for clearance during lactation differ from pregnancy because the rat-based PBPK results do *not* indicate reduced clearance during lactation as they did for pregnancy; thus, reduced clearance during lactation was not considered for the lactating women subgroup.

Regarding Figure B-6, since use of the PBPK model versions for pregnancy and lactation involve integrating exposure and dosimetry over the weeks from conception and/or birth, it is helpful to use a smooth function with a simple form which captures the primary time-dependent changes in the various parameters, including clearance. The U.S. EPA decided that it would be efficient and reasonable to only consider simple, non-mechanistic functions, balancing the desire to capture the primary time-dependent changes against the potential problems in identifying parameters that can occur with more complex equations. A quadratic equation appears to satisfy these criteria appropriately, and the U.S. EPA does not believe that more meaningful information could have been extracted with an alternate function form.

It is not clear whether the apparent "dip" in clearance observed late in pregnancy (week 36 vs. weeks 32 and 38) is due to real changes in clearance or if it is due to experimental variability and measurement error. Consequently, without a supporting biological mechanism, the U.S. EPA considers the current model, which captures the long-term trend although not the shorter-term variation, to be appropriate.

The post-partum data in Figure B-6 are also taken from Aboul-Khair et al. (1964) – the same post-partum data shown in Figure B-5 just above. From the Aboul-Khair et al. (1964) data and figure, it appeared to the U.S. EPA that there is an overall downward trend in clearance starting around GW 30 and continuing through birth into the post-partum period. So, the data were included to guide the quadratic curve-fit to capture that trend.

It is clear to the U.S. EPA that increased iodide clearance during pregnancy is widely believed to occur, and the data of Aboul-Khair et al. (1964) are consistent with that assumption. However iodide clearance, per se, can only be determined by simultaneously measuring iodide blood levels and urine concentration or excretion rate in the same individual, and the literature search conducted by the U.S. EPA only identified the Aboul-Khair et al. (1964) paper with clearance data. However, the review of DeLange (2004) questions that assumption and instead suggests that clearance does not change during pregnancy.

While GFR may be related to cardiac output (QC) in general, it seems likely that it is the rate of kidney perfusion (QK) that is the actual determining factor. As currently formulated the model *QK does not change* during pregnancy. Increases in QC primarily serve the developing fetus, uterus, and breast tissues.

Comment A1-c: None of the reviews identified other publications or data; however, one reviewer recommended obtaining data on differences in urinary clearance data outside the perchlorate and iodide literature, and another reviewer suggested obtaining additional data to cross check assumptions regarding iodide uptake and renal clearance during pregnancy and early postpartum. No specific references were provided.

Response A1-c: The U.S. EPA agrees that changes in clearance of other substances would be informative, provided that such clearance was GFR-mediated or -determined. The U.S. EPA did seek to identify such data but no additional data were found, and therefore no additional data were included in the document. It is noted that data on clearance of pharmaceuticals is often proprietary and therefore not readily available in the open literature. Also, many if not most pharmaceuticals have rates of clearance that are determined by metabolism that would not be appropriate for extrapolating in this case.

Comment A1-d: With respect to urinary clearance rates for the infant and older child, six of the reviewers agreed with the values used and none of the reviewers disagreed or suggested alternative values. One reviewer referred U.S. EPA to alternative guidance for urinary clearance in neonates, infants, and children but did not find any evidence to contradict the assumptions used. Another reviewer noted that the estimates used for urinary clearance in infants and children reflect published GFR values. One reviewer recommended emphasizing inter-individual variability in the discussion and describing it quantitatively.

Response A1-d: It is clear that an explicit analysis of inter-individual variation would be informative. See response to G3-a for a discussion on possible alternate approaches to estimating clearance rates.

Comment A1-e: One reviewer identified inconsistencies to be clarified, particularly with respect to scaling, and areas for future research, e.g., a consistent treatment of the urinary clearance process for various life stages.

Response A1-e: The U.S. EPA's goal was to assure consistency in handling iodide and perchlorate clearance. A clarification was added to the beginning of Section 3. For example, when considering reduced clearance during lactation, if iodide clearance was reduced by 60% then the U.S. EPA also reduced perchlorate clearance by 60%. In this regard the U.S. EPA was indeed consistent in changing the perchlorate and iodide clearance parameters. However, Clewell et al. (2007) reduced perchlorate clearance during lactation 60% from the "average adult" value found by Merrill et al. (2005), but did *not* reduce iodide clearance. The U.S. EPA chose not to consider that option as it appears inconsistent.

On units of clearance, when simulating an individual the rate of urinary clearance of "x" is:

$$RAU_x \text{ (mg/hr)} = CLU_x \cdot CVK_x,$$

where the (scaled) clearance constant, CLU_x, has units of L/hr (equivalent to volume of blood cleared per time), and CVK_x is the concentration in the kidney venous blood and has units of mg/L. Thus the units of the clearance rate (RAU), clearance constant (CLU) and blood concentration are all consistent.

However, as is often the case in PBPK modeling, the clearance rate constant is assumed to scale allometrically, by $BW^{0.75}$, and is therefore defined as:

$$CLU_x \text{ (L/hr)} = CLUC_x \cdot BW^{0.75}.$$

In fact this equation defines $CLUC_x$ and in no way contradicts the physics of the problem, which is appropriately represented by the equation for RAU. Further, given the units of CLU as shown, and that BW has units of kg, it follows that the units of CLUC *must be* $L/h/kg^{0.75}$. Since the model code describes urinary clearance using these two equations, with $BW^{0.75}$ scaling, it follows that the listing of CLUC by Clewell et al. (2007) and Merrill et al. (2005) as having units of L/h/kg is a simple typographical error.

The U.S. EPA does not believe that the document will be improved by including this exposition, since the key points area already included, so no changes have been made.

Furthermore, the U.S. EPA considers use of $BW^{0.75}$ to be a good rule-of-thumb, both for scaling across species and among individuals within a species, in the absence of other data. However, very young children are not the same as small monkeys (despite euphemistic references) and even the data for basal metabolic rate variation across species shows scatter around the primary allometric relationship that cannot be completely described by a simple power function. Therefore species- or substance-specific data may well depart from this general relationship, and therefore we choose to use the more specific data over the generality when such data are available. The suggested paper by Johnson (2008) provides data which strongly indicate a departure from this scaling in neonates, which supports the use of clearance data in human children that departs from this relationship.

Regarding the "GFR-based scaling" in Figure B-2, this scaling is defined by equation B3, not B1 as the draft document erroneously indicated. The scaling involves a combination of scaling by $BW^{2/3}$ to approximate dependence on body surface area (SA) and a correction factor, the specific growth rate (SGR), to account for the fact that infant excretion falls below what one would predict based on SA alone, with SGR being a function of infant age. Since there is variation in individual BW at any given age, when this function is applied to a set of individual data with known ages and BW, the result is not a smooth function of age but reflects the variation in BW with age. Appendix B, Section B.3 has been modified slightly to correct this error and clarify these points.

Comment A1-f: One reviewer requested clarification on Figure B-4 and for the statement that the U.S. EPA considers its urinary clearance estimates in infants and children to be scientific estimates and not bounds.

Response A1-f: General statements have been added to the Introduction (section 1) to explain the reasons and approach for describing population average behavior, and details about the handling of urinary clearance also have been added to section 3.1. In addition, the text under Figure B-4 has been expanded to include further explanation.

If the normalized Lloyd et al. (1985) data (yellow diamonds in Figure B-4) are simply taken as a collection of values, assumed to be independent of BW, then one can estimate a mean, standard deviation, etc. The "Lower 95% of Lloyd et al.(1985) " line is simply a horizontal line plotted at a y-value equal to lower 95% confidence limit on the mean of the data. The data average line is likewise determined by combining the normalized Lloyd et al. (1985) and Chin et al. (1982) data, irrespective of BW, calculating the average of those values, and plotting a horizontal line with that value.

The primary point of this plot is to show that, while the normalized data (Clu/BW values) show some downward trend with BW, the error between the data and assuming BW^1 scaling, which corresponds to the horizontal line (when normalized to BW) is not substantially worse than using $BW^{2/3}$ or $BW^{0.75}$. There is not a strong BW-dependent trend in the data such that one of the later scaling curves better describes the data, and in fact those two curves substantially over-predict clearance for many of the individuals (data points) shown.

The scaling used by the U.S. EPA corresponds to the "~ Adult average" line in the plot. As shown, this scaling comes quite close to the data average and is above the 95% confidence limit on the mean of the Lloyd et al. (1985) data. Thus, it is considered an estimate of the population average, rather than a (lower) bound.

B. Breast-milk ingestion

Parameter-Specific Charge Question B1. **Infants are generally known to consume very little milk or formula on the first day of life, with ingestion quickly increasing over time. However the first time-point for which ingestion data are available for infants is at 7 days, which EPA extrapolated back to 0 ingestion at time=0 in its analysis (birth; Figure 1). The breast-milk ingestion rate was estimated based on mean values reported in Arcus-Arth et al. (2005), while the water ingestion used for the breast-feeding mother was the 90th percentile value from U.S. EPA (2004).**

Is EPA's extrapolation and rationale transparently and objectively described? Does this function appropriately characterize the available data and information? Are there other data that could be used to obtain a better or equally valid alternative estimate of mean breast-milk ingestion rate for infants in the first few days of life? Should an estimate other than the mean be used to determine the breast-milk ingestion rate?

Comment B1-a: None of the reviewers disagreed with the U.S. EPA's extrapolation. Five reviewers explicitly stated that the U.S. EPA's explanation was objective, and three noted that it was transparent. One reviewer pointed out that the modeling of perchlorate and iodine kinetics

in the neonate is highly uncertain, making this one of the weakest parts of the analysis. The reviewer recommended that this uncertainty be more clearly articulated in the document. One reviewer noted that the characterization would be confusing for readers that were not modelers.

> Response B1-a: Additional discussion of the uncertainty surrounding model predictions for neonates and fetuses was added to the document (Section 5.2). The reviewer is correct that modeling of perchlorate and iodine in the neonate is more uncertain than the adult. No data are available for the validation of the percent RAIU inhibition in the neonate or fetus. However, a small amount of data available for neonates was compared to model predictions of urinary radioiodide excretion (Clewell et al., 2007 – Figure 9). In the fetus, data were available to compare with model predictions of thyroid and blood radioiodide (Clewell et al., 2007 – Table 3) and serum perchlorate (Clewell et al., 2007 – Figure 10).

Comment B1-b: None of the reviewers disagreed with the use of the data in Arcus-Arth et al. (2005). One reviewer suggested that there are data in the literature for intake on days 1, 2, 3, 4, and 5, and that the values on days 4 and 5 are consistent with what was reported in Arcus-Arth, et al. However, no specific additional references were provided. Another reviewer asked that the decision to use Arcus-Arth et al. be clarified.

> Response B1-b: Further explanation on the use of Arcus-Arth et al. (2005) was added to Section 3.3.1. Data for days 1-5 (tabulated in Arcus-Arth et al., (2005) and originally reported in Casey et al., (1986)), in addition to other data for the first two months after birth, were used to derive the equation for the breast-milk ingestion rate. This approach is described in detail in Section 3.3.1 of the document. Data reported by Arcus-Arth et al. (2005) were chosen as the most complete and most recent data available that could be used to derive breast-milk ingestion rates and that included data for very young infants. The Arcus-Arth et al. (2005) study was designed to represent the infant population whose mothers follow the American Academy of Pediatrics (AAP) recommendations. It was a meta-analysis using data from various studies in the peer-reviewed literature, and intake was calculated on a body weight basis.

Comment B1-c: Two reviewers agreed with the extrapolation from day 7 to day 0, while three expressed questions or concerns about it. One reviewer stated that the extrapolation was not warranted because the newborn was not a subgroup used in the assessment of relative sensitivity of lifestages. The second questioned the abrupt increase in milk ingestion during day 1 and between days 1 and 7; however, that reviewer concluded that the mean breast-milk ingestion rate might be robust enough for use. Another reviewer stated that the use of body weight as a surrogate for age is illogical and recommended developing an expression for milk ingestion in terms of volume per body weight per day as a function of age. That expression could then be used to convert to the model parameter for the milk ingestion rate.

> Response B1-c: As a result of reviewer comments, the U.S. EPA has moved from using a power function to relate BW to breast-milk ingestion to using a Hill-function that describes breast-milk ingestion as a function of age. This change is shown in Section 3.3.

Briefly, while the newborn infant (< 7 days old) was not explicitly considered in this analysis, it is necessary to describe breast-milk ingestion the first 7 days of life as accurately as possible because the perchlorate ingested during this timeframe affects the %RAIU inhibition at 7 days of age, the neonate age that was first considered in this analysis. Additionally, the data tabulated in Arcus-Arth et al. (2005) for these few days after birth were first reported in Casey et al. (1986). Using these additional data, (now included in Figure 3-1), a Hill-function describing breast-milk ingestion rate (mL/hr) as a function of age (days) was derived and used in the PBPK model in place of the initial U.S. EPA power function relating BW (kg) to breast-milk ingestion (mL/hr). The Hill-function is a better predictor of the data, especially during the first 7 days after birth, than the table function originally implemented in the model by Clewell et al. (2007) and was easily implemented in the PBPK model code.

Comment B1-d: Two reviewers questioned the use of a mean value for infants and recommended further explanation of the rationale. One reviewer stated that using the 90th percentile for intake would lead to an unrealistically high estimate for milk consumption. Another reviewer thought that if the purpose was to determine the relative difference in iodide uptake inhibition for various subgroups, then the mean should be used consistently for all exposure and pharmacokinetic parameters throughout the analysis. Two reviewers recommended better accounting for variability. One noted that whether the mean should be used depends on steps later in the process and how variability is considered. This reviewer added that using mean values and the approach to computing the milk ingestion rate parameter precluded a fuller description of variability in iodide uptake inhibition. The other reviewer recommended using a distributional rather than a point calculation approach due to the large population above the 90th percentile and the potential "spread" of exposure factors above that percentile.

Response B1-d: The relative sensitivity analysis reported in Table 4-3 was conducted using a fixed dose-rate, 7 μg/kg-day, rather than any particular water ingestion value. The subsequent analysis (Table 4-5) where % RAIU inhibition is estimated for each lifestage does use upper percentile ingestion rates because the U.S. EPA's intent is to protect the entire population. However, as now stated in section 3.3 ("Post-natal PBPK Modeling") an average ingestion rate is used for breast-milk ingestion because in that case the neonate's exposure to perchlorate is due to the mother's ingestion, and an upper bound is used for the mother's ingestion. Assuming that the infant's ingestion of breast milk and the mother's ingestion of tap water vary independently, using an upper bound for both would be using a "double" upper bound for this lifestage alone, and therefore inconsistent with the bound used for other lifestages. Considering the breast-feeding mother and child as a unit, breast-milk ingestion may be thought of as an "internal" flow, for which the model represents the biological average rather than a distribution.

The U.S. EPA selected the 90th percentile drinking water intake value for most of the subpopulations evaluated in this report in order to explore the potential effects of high end exposure to perchlorate from public water systems. The approach is consistent with the Agency's *Guidelines for Exposure Assessment* (1992) and with the U.S. EPA policies and procedures for deriving health based drinking water values including Maximum Contaminant Level Goals (MCLG), Health Advisory values (HA), and Health Reference

Levels (HRL). The U.S. EPA acknowledges that modeling a complete distribution of water ingestion would be informative; however, due to time and data constraints the U.S. EPA selected a high-end exposure estimate as the most appropriate means to explore the potential effects of drinking water exposure on subpopulations.

The U.S. EPA does not believe that using mean drinking water intakes would characterize the high end exposures to perchlorate that may occur as a result of drinking water consumption. Similarly, the use values in excess of the 90^{th} percentile would be inconsistent with the Agency's policy to focus on realistic exposure scenarios and to avoid worst-case scenarios. The U.S. EPA further notes that less than one percent of public water systems reported detecting perchlorate at concentrations greater than 15 µg/L. Therefore, by evaluating populations consuming the 90^{th} percentile of drinking water with concentrations of perchlorate at 15, 20 and 24.5 µg/L, the U.S. EPA is providing a realistic high-end exposure estimate. See also the response to comment C1-c.

The primary points from this explanation have been added to Section 4.3.

C. Water ingestion

Parameter-Specific Charge Question C1. **For pregnancy, EPA used a normalized (90th percentile) water ingestion rate of 33 mL/kg-day (U.S. EPA 2004), which was multiplied by the maternal BW as described by the PBPK model growth-functions during pregnancy to obtain total water ingestion for the mother.**

Is EPA's approach and rationale transparently and objectively described? Is this approach appropriate for characterizing the upper-bound for ingestion of pregnant women? Are there other approaches or data that could be used to obtain a better or equally valid alternative estimate for this parameter? (Note that the self-reported body weight values in U.S. EPA (2004) indicate the same average body weight for pregnant women as for non-pregnant; data appears inaccurate, so the PBPK model body-weight description was used instead.)

Comment C1-a: Four reviewers agreed with the U.S. EPA's approach, and three reviewers explicitly stated that the approach was objectively described and transparent. One reviewer noted that the water ingestion was not extensively discussed and questioned if modifications were made to the variable in the Clewell et al. model. One reviewer stated that the U.S. EPA was inconsistent in choosing upper bounds or means for various parameters and thought that if the purpose was to determine the relative difference in iodide uptake inhibition for various subgroups, then the mean should be used consistently for all exposure and pharmacokinetic parameters throughout the analysis. One reviewer recommended a distributed zonal analysis rather than point calculations.

Response C1-a: See response to B1-d. Additionally, Clewell et al. (2007) did not describe water ingestion rates explicitly, but rather utilized constant dose rates (mg/kg-day), thus the water ingestion variables added by the U.S. EPA were new. As noted above and already clearly stated in the document, relative sensitivities were evaluated at a fixed dose-rate 7 µg/kg-day. Using such a fixed dose-rate provides a consistent basis for

evaluating relative sensitivity. The dose-rate might otherwise be calculated as the product of the water ingestion rate and water concentration, but for the relative sensitivity analysis it was set directly.

Comment C1-b: Four reviewers requested further explanation for how the 90th percentile value was derived and why it was used. Two of these reviewers recommended explaining why the 90th percentile value, rather than other values (such as the median or 95th percentile), was chosen for the computations.

Response C1-b: See response B1-d.

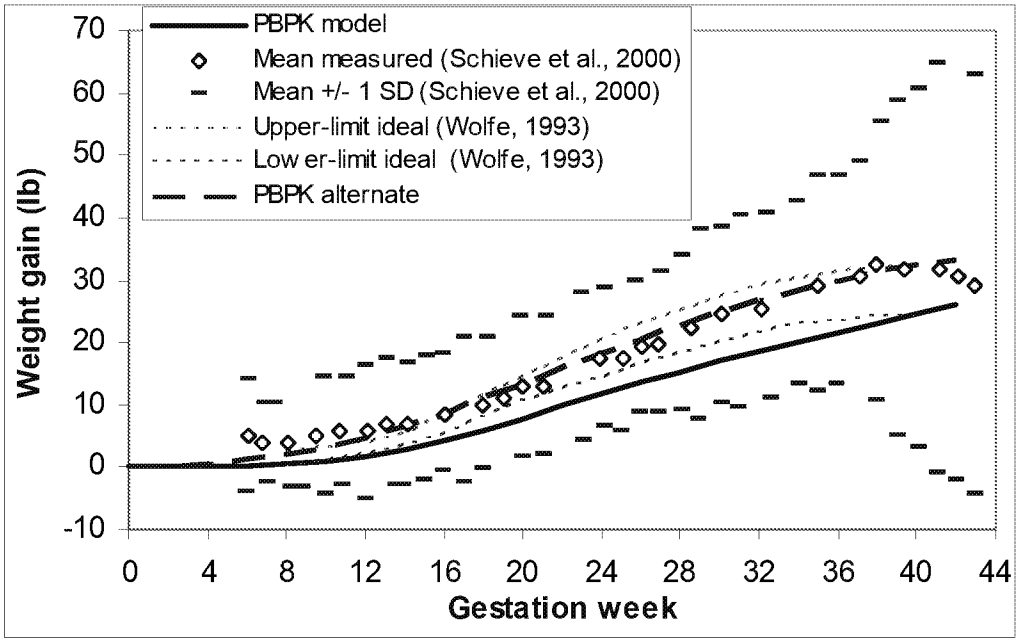
Comment C1-c: Two reviewers noted that the 90th percentile value was associated with a relatively small sample size (n = 65). One reviewer suggested this may be an underestimate and questioned the importance of the assumption and the sensitivity to the results. The other reviewer suggested using ingestion rates from Ershow et al. (1991), or to justify why they should not be used. This reviewer also questioned why the U.S. EPA specified total water ingestion rate but actually used the community water ingestion rate.

Response C1-c: The U.S. EPA selected community water ingestion for the analysis to characterize the high end exposure to perchlorate from public water systems (as opposed to bottled water or private well water which is captured in the total water ingestion). For a regulatory action under SDWA, the U.S. EPA's interest is in the impact of perchlorate in direct and indirect water. The reviewer is correct and this correction to the text has been made, as the analysis reflects that focus and that portion of water intake only. The U.S. EPA believes Kahn and Stralka (2008) and U.S. EPA (2004) are more recent and more appropriate data by which to evaluate the sensitive subpopulations of concern than is Ershow et al. (1991). The data from Ershow et al. (1991) were derived using data from the 1977-78 USDA Nationwide Food Consumption Survey, which is now 30 years old. . See also the response to B1-d.

Comment C1-d: One reviewer questioned the accuracy of the model growth-functions during pregnancy for estimating the body weight of pregnant women and suggested the U.S. EPA validate the weight estimates using NHANES data.

Response C1-d: While the CDC collects data on maternal weight gain and other health indicators for pregnancy, these appear to be just reported as total weight gain (from conception to just before birth), reported in the form of percent of population falling into various categories ("Under weight", "Normal weight," etc.), and do not include information on specific growth. However Schieve et al. (2000) reports BW gains during pregnancy from data for 3,511 mother-infant pairs from the 1988 National Maternal and Infant Health Survey, and Wolfe (1993) provides "upper-limit" and "lower-limit" values for ideal weight gain during pregnancy. Model-predicted BW gain is plotted against these published values below (the solid, dark-blue line is with the original model; the long-dashed, light-blue line is with PBPK model growth curves adjusted upward; the

mean and mean ± 1 SD are data from Schieve et al. (2000), and the "Upper/Lower-limit ideal" are from Wolfe (1993)).



Except for the apparent plateau in the data starting around GW 38, the shape of the model growth curve matches the observed growth curve quite well. While the curve falls somewhat below the observed mean (Schieve et al., 2000), it is well within one standard deviation of the mean, and since these were data not used in specifying the model, the agreement appears to be quite good.

Note that the data for the last few time points represent women who had not already given birth by that point; e.g., women who gave birth at GW 40 would not be included in the population represented at GW 42. So, the apparent plateau should not be construed as meaning that an individual woman's body weight would plateau or begin to decline in the last few GWs, but likely indicates that women who had the highest increase in BW by GW 38 (when the peak in the mean value occurs) gave birth in that week and so were not included in the population analyzed at later weeks. Since there is a tendency to induce labor before the child becomes too large to be safely delivered, the downward trend is then explained as a population shift, whereas the model growth-curve represents the change in a particular individual.

Finally, to test the sensitivity to BW, an alternate model version with the growth curve shifted upward was tested and compared to the original model. RAIU inhibition was evaluated at GW 40, given an exposure to 7 μg/kg-day (the POD). With the model as specified by the authors the RAIU inhibition predicted for the mother and fetus were 6.10 and 11.0%, respectively, and with the BW increased to better match the observed mean, the model predicted 6.14 and 11.1%, respectively. Thus the sensitivity of model predictions to changes in this range is negligible.

This information and figure were added to Section 4.1.1.1, Figure 4-1.

Comment C1-e: One reviewer recommended considering other approaches for estimating water ingestion for pregnant women. One suggestion was to consider water requirements for women in hot climates and choose a value somewhat above the 3.0 L/d considered an "adequate intake" by the Institute of Medicine (2004). The other suggestion was to pick a plausible upper bound from a cumulative distribution, and the reviewer offered that a value between 3.5 and 4 L/d seemed reasonable.

> Response C1-e: See response B1-d. The U.S. EPA recognizes that many women also drink bottled water and other beverages, for which any contribution to perchlorate exposure would be included in the "TDS" value. Thus the actual tap water ingestion is likely to represent only a fraction of the liquids ingested. Further, the U.S. EPA's objective is to estimate *actual* tap water ingestion in the U.S. population and the U.S. EPA believes the values currently used in the document are representative of the U.S. population exposure to tap water.

Parameter-Specific Charge Question C2. **For lactation, EPA used a fixed total (90th percentile) water ingestion rate of 2959 mL/day (U.S. EPA 2004), with the rationale that while the woman's weight and self-water demand are expected to drop after pregnancy (as described by the PBPK model time-dependent weight equations), the demand for milk production would be increasing, and the reported value was not for a specific age-range of child.**

Is EPA's approach and rationale transparently and objectively described? Is this an appropriate value to use for the ingestion rate of lactating women? Are there other better or equally valid alternative approaches or values that could be used?

Comment C2-a: Six reviewers agreed with the U.S. EPA's approach and five of these stated that the approach was transparent and adequately described. One reviewer requested clarification of the objectives of the analysis and reiterated that, if the purpose is to determine the relative difference in iodide uptake inhibition for different subgroups, then the mean should be used consistently for parameters throughout the analysis to avoid bias. One reviewer suggested that a probabilistic analysis would provide further insight and that a population/distribution-level analysis could be used to test the model in relation to data from Pearce et al. (2007) and Kirk et al. (2005, 2007).

> Response C2-a: The fixed ingestion rate of 7 μg/kg-day was used evaluating relative sensitivities, which is consistent in that the results show the differences in biological sensitivity, rather than differences due to changes in ingestion rates. As described in Response G1-a, sufficient data on NIS distributions that would be needed for a probabilistic analysis are not available at this time and the task of collecting and integrating the requisite information is beyond the scope of the current effort. The objectives of this analysis were elaborated upon in Section 1 of the document as well as

rationale for obtaining model predictions for the average individual, but using 90th percentile water ingestion, in each subgroup.

Comment C2-b: One reviewer questioned why the ingestion rate was substantially higher during lactation than pregnancy and recommended adding rationale for using a fixed ingestion rate. Another reviewer requested a better explanation for why a fixed ingestion rate was used, given the higher ingestion rate in lactating women on a mL/kg-day basis.

Response C2-b: As reported in Tables 6.3A-C in U.S. EPA (2004), the water ingestion rate of a lactating mother is greater than that of a non-pregnant or pregnant woman. This analysis reflects the recent data collected such that the water ingestion rate for the lactating woman (2.96 L/day) is greater than the non-pregnant (0.032 L/kg-day x 66kg = 2.11 L/day) and pregnant woman (0.033L/kg-day x 69-78kg = 2.18-2.57 L/day). Furthermore, instead of adjusting the lactating mother's water ingestion based on BW, which would decrease over time as the mother lost her weight gained during pregnancy, the water ingestion rate was kept constant. It is not known how the lactating mother's water ingestion changes over the first few months after giving birth. While it is possible that the mother's water ingestion may simply drop in proportion to her body weight, the U.S. EPA also considered the possibility that as the growing infant ingests an increasing volume of milk this would offset the reduced water consumption that would otherwise be expected to accompany a reduction in body weight. Therefore total water ingestion was kept constant, in the face of this uncertainty. This assumption leads to a higher predicted perchlorate dose, and hence effect, than if the mother's ingestion were assumed to decrease with her body weight.

Comment C2-c: Three reviewers questioned the use of the 90th percentile rather than the 95th percentile and asked for further explanation. One reviewer was concerned that a large number of mother-infant pairs are above the 90th percentile. Another reviewer suggested the U.S. EPA provide the rationale for selecting 2,959 mL/day at the 90th percentile and thought that providing the complete distribution of the water ingestion estimates would be helpful. The third reviewer asked why the U.S. EPA specified total water ingestion but used direct and indirect community water ingestion. This reviewer, noting the small sample size for the current value, also recommended using ingestion rates from Ershow et al. (1991), or justifying why they should not be used.

Response C2-c: See response B1-d.

Comment C2-d: One reviewer acknowledged that there are few data on the water needs of lactating women but presented the IOM (2004) argument that the intake of non-pregnant women added to the fluid output in breastfeeding provides a reality check on water ingestion rate. This reviewer recommended considering other approaches for estimating water ingestion for pregnant women. One suggestion was to consider water requirements for women in hot climates and choose a value somewhat above the 3.8 L/d considered an "adequate intake" by IOM (2004). The other suggestion was to pick a plausible upper bound from a cumulative distribution, and the reviewer offered that a value around 4 L/d seemed reasonable.

Response C2-d: See responses C1-e and B1-d.

The U.S. EPA seeks to identify a reasonable upper bound on tap-water consumption by women in the U.S. This ingestion rate may be less than an "adequate" intake, especially for women of warmer climates, since most of the U.S. has a moderate to cool climate and most people ingest beverages in addition to tap water to fulfill their water needs.

Breast-milk ingestion rises to an average of 25 ml/hr or 0.6 L/day in the first couple of weeks after birth, and continues rising to about 30 ml/hr or 0.72 L/day by 2 months. This is somewhat less than the exposure estimate change from 2.57 L/day for the GW 40 mother to 2.96 L/day for the lactating mother, but since a significant portion of breast milk will be lipids, an increase of 0.4 L/day appears appropriate.

Parameter-Specific Charge Question C3. **For bottle-fed infants, EPA made extrapolations of the 90th percentile water-ingestion in early life based on measurements made for the age ranges: 0-30 days, 1-3 months, and 6-12 months (points in Figure 2, upper panel). For the purposes of this analysis, bottle-fed implies feeding with formula requiring the addition of water.**

Is EPA's extrapolation and rationale transparently and objectively described? Does the overall function used to represent the changes in ingestion with age (and body weight) appropriately characterize the available data and information? Are there other data that could be used to obtain a better or equally valid alternative estimate of water ingestion rate for infants in the first few days of life (e.g., 7-day old)? The water ingestion rates used by EPA are based on 90th percentile ingestion data and thus are likely to exceed (minimal) physiological needs of infants as defined in nutritional guidelines. Are the water ingestion rates used by EPA reasonable in comparison to the physiological needs of infants at these various life stages? Are there other approaches or data (e.g., see the FDA memo) that could be used to obtain a better or equally valid alternative estimate for this parameter?

Comment C3-a: Seven reviewers agreed with the U.S. EPA's approach, and four of these reviewers stated that it was transparently and objectively described. One reviewer requested clarification of the objectives of the analysis and reiterated that, if the purpose is to determine the relative difference in iodide uptake inhibition for different subgroups, then the mean should be used consistently for parameters throughout the analysis to avoid bias. One reviewer noted that the reason for using a quadratic equation was not provided. Another reviewer stated that it was doubtful that using a single point estimate would provide an adequate understanding of the potential range of exposures and corresponding doses for bottle-fed infants.

Response C3-a: The fixed ingestion rate of 7 µg/kg-day was used for the relative sensitivity evaluation, thereby eliminating dependence on water ingestion for that calculation. Because data are not available for every age, it was necessary to fit a smooth curve to the data to predict water ingestion at the "in-between" ages. A quadratic equation was determined to provide an adequate fit to the data, consistent with the objective of performing a rapid and relatively simple analysis, and thus was used to estimate the ingestions at different ages. The U.S. EPA does not believe that using a 90th percentile ingestion rate provides an understanding of the range of potential effects from

different exposure scenarios, but rather characterizes the realistic, high-end exposure to perchlorate that may occur as a result of drinking water consumption.

Comment C3-b: One reviewer asked why the calculation was not scaled to 2 and 3 years and whether 0-7 days should represent another group or be removed (i.e., use 0-7 days or 7-30 days). Another reviewer questioned why the emphasis is placed on the section of the curve (i.e., the first few days after birth) that is not used in the lifestage analysis or supported by data.

Response C3-b: As stated in Response B1-c the first few days after birth are important in determining the infant's perchlorate concentration at day 7, and thus some estimate of intake must be used. Emphasis was not intended to be placed on the first 7 days following birth; however, it was necessary to make an estimate of ingestion during this timeframe. It did not seem logical to extrapolate the curve fit to data from Kahn and Stralka (2008) (shown in Figure 3-2A) such that the 1 day old infant consumes almost as much as the 7 day. Thus, the extrapolation was made back to 0, as shown in Figure 3-2B.

Additionally, a distinct set of computer files is used to simulate perchlorate dosimetry in older children (age 1 year and above), and dosimetry in older children is expected to have no dependence on exposures during infancy. Thus, the infant exposure calculation was not scaled to older children, and the two age ranges were analyzed separately.

Comment C3-c: One reviewer suggested that the U.S. EPA look at a report from a public health agency in Québec that has data on water ingestion rates for infants 8 weeks of age. One reviewer agreed that it was reasonable to use nutritional guidelines and that it would be useful to compare water consumption with what one would expect given nutritional guidelines and typical formula recipes, the nutritional guidelines would not lead to a reliable upper bound value for water consumption. None of the reviewers recommended using the approach outlined in the FDA memo as a better alternative to what was presented in the report.

Response C3-c: The values reported in a document published in Québec (Direction Risques biologiques, environnementaux et occupationnels, Institute national de santé, and Unité de recherché en santé publique, 2004) for bottle-fed only infants of 8 weeks (56 days) of age are slightly less than the values used by the U.S. EPA in this analysis. The 90^{th} percentile water ingestion values in the Québec report were 981 mL/day or 179 mL/kg-day for 8-week-old bottle-fed infants. The U.S. EPA did not estimate percent inhibition of radioiodide uptake for the 8-week old bottle-fed infant. These data provide support for the use of the 90^{th} percentile estimates from Kahn and Stralka (2008), but do not suggest a need to change the estimate for bottle-fed infants.

Comment C3-d: One reviewer recommended using nutritional guidelines to estimate the total water-ingestion rate. One reviewer offered an alternative approach for estimating ingestion rates for the first few days of life in which the data on breast milk consumption for the first few days (e.g., from Casey et al., 1986; Neubauer et al., 1993) are used. This reviewer suggested comparing literature values for breast milk consumption on days 1-7 to the values predicted for bottle-fed infants using the $1\text{-}e^{-day}$ function.

Response C3-d: Breast milk consumption for the first few days of life was tabulated in Arcus-Arth et al. (2005) from data reported by Casey et al. (1986). These data were considered in determining the breast milk ingestion rate for the breast-fed infants. Since individual ingestion can vary above or below nutritional guidelines and the U.S. EPA's goal was to estimate actual ingestion, the values from Kahn and Stalka (2008) were used in this analysis.

D. Perchlorate concentrations in formula

Parameter-Specific Charge Question D1. **EPA used 1.42 µg/L as the concentration of perchlorate in formula for bottle-fed infants. This estimate was based on information from FDA's Total Diet Study, supported by Pearce et al.'s (2007) findings.**

Is EPA's approach and rationale transparently and objectively described? Is 1.42 µg/L an appropriate value to use for the concentration of perchlorate in infant formula? Are there other better or equally valid alternative approaches or values that could be used?

Comment D1-a: Seven reviewers agreed with the U.S. EPA's approach, and five of these stated it was transparently and objectively described. One reviewer recommended adjusting the intake of perchlorate from infant formula to result in a daily exposure at the point of departure in order to provide results for a consistent comparison across all subgroups. Another reviewer recommended making the description more transparent and providing a sample calculation for Table 4 to show how perchlorate intake for bottle-fed infants was estimated.

Response D1-a: The bottle-fed infant formula contribution to perchlorate exposure was not set to result in a daily exposure equal to the point of departure (POD) because the concentration in infant formula should be reflective of the concentration in formula rather than the POD. The POD (7000 ng/kg-day or 7 µg/kg-day) was used in Table 4-3 for each lifestage to provide for a consistent comparison across lifestages. The FDA TDS data was added to the document and is shown in Table 4-4 along with the market basket averages and the overall average. A more detailed description of the calculation that yielded 1.42 ppb was added to Section 4.3.

Comment D1-b: One reviewer recommended that the U.S. EPA provide additional rationale for the selection of 1.42 µg/L, note in the document that the concentration values in Pearce et al. ranged from 0.2 to 4.1 ppb, and examine the sensitivity in uptake for a range rather than an average value. Another reviewer expressed concerns that the composite samples and detection limit (1 µg/L) of the FDA data do not provide an indication of higher end exposures. The reviewer also argued against using data on ready-to-eat formulas because the infants receiving that type of formula would not be part of the population drinking tap water. The reviewer recommended using either the highest value from the FDA study (3.6 µg/L) or a high value from the Pearce et al. (2007) study, based on measurements of undiluted (but intended to be diluted) formula (~3 µg/L). The reviewer added that better and more extensive measurements of perchlorate in infant formula are desirable.

Response D1-b: Additional rationale for the use of the 1.42 μg/L (ppb) from the FDA TDS study (Murray et al., 2008) was added to the document in Section 4.3. The U.S. EPA selected the Total Diet Study data (Murray et. al, 2008) to represent the dietary intake of perchlorate because TDS is the best available, nationally representative estimate of dietary exposure to perchlorate for the majority of the sensitive subpopulations of concern, including infants and children.

Model simulations were performed to examine the effect of using 1 ppb or 3.6 ppb (an upper end value from Pearce et al. (2007) instead of 1.42 ppb. Results of this sensitivity analysis were added to the document in Section 4.3.

The contribution of concern under SDWA is represented by the consumption of drinking water used to reconstitute powdered formula and formula concentrate. However, the U.S. EPA believes it is reasonable to compare the TDS data to an average value from Pearce et al. (2007) that included both ready-to-eat and concentrated formulas. After powdered formula is reconstituted with water, the concentration in the final product will be the sum of the amount in the powdered formula and that in the tap water. Since the perchlorate concentration in un-reconstituted powdered formula has not been reported, the U.S. EPA assumed that the contribution from the powdered formula after reconstitution (when the formula is ready for consumption) would be the same as the concentration in ready-to-eat formula. This is equivalent to assuming that ready-to-eat formula is made by reconstituting powdered formula with perchlorate-free water.

The U.S. EPA agrees that better and more extensive measurements of perchlorate in infant formula are desirable.

E. Radioiodide excretion into breast-milk by NIS

Parameter-Specific Charge Question E1. **In the model, EPA included perchlorate inhibition of NIS radioiodide excretion into breast milk, as well as inhibition of radioiodide transport by perchlorate for all NIS-containing tissues, thereby making the code consistent with the model description in Clewell et al. (2007).**

Is this inclusion appropriate? Are the impacts of this inclusion transparently and objectively described?

Comment E1-a: Seven reviewers agreed with the U.S. EPA's approach and stated that it was objectively and transparently described. One reviewer recommended reconsideration of Pearce et al. as these data do not suggest that there would be an effect of perchlorate on the excretion of iodine in breast milk; therefore, inclusion of this model feature may not be accurate. Another reviewer recommended adding a section towards the end that discusses the impacts of perchlorate inhibition.

Response E1-a: U.S. EPA is retaining in the model the perchlorate inhibition of radioiodide excretion in breast milk and believes it is consistent with the data in Pearce et al. (2007). The impact of including NIS inhibition of iodide transport into breast milk the model-predicted iodide concentration in breast milk by ~3% at a maternal dose equal to the point-of-departure (7 μg/kg-day). This small decrement is consistent with the

observations of Pearce et al. (2007), since the change is less than the variability seen in those samples. However, it should be noted that this reduction is essentially additive. That is, if the effect of the perchlorate alone on the infant is ~3% and the reduction in breast-milk iodide is ~3%, then the net effect on the amount of iodide taken up by the infant thyroid will be a ~6% reduction.

Published data have not shown a decrease in breast-milk iodide at low levels of perchlorate exposure. However, high-level perchlorate exposures (Kirk et al., 2005) and exposures to thyiocyanate (Laurberg et al. 2004) have been shown to decrease breast milk iodide. A full discussion of the impacts of perchlorate inhibition is beyond the scope of this document, but is available in the National Academy of Sciences review (NCR, 2005).

Comment E1-b: One reviewer noted that the rationale for scaling NIS levels to body weight was not clear and recommended review of studies (Faggino et al. and others) that suggest that scaling may not be appropriate as NIS expression changes over the course of development.

Response E1-b: See response to G3-a. U.S. EPA has reviewed the information recommended by the reviewer and has decided to retain the NIS scaling as originally described by the models' authors (Clewell et al. 2007 and Merrill et al. 2005).

Additional Reviewer Comments

Comment 1: One reviewer stated that the U.S. EPA should have considered easier and more straightforward approaches, e.g., Lorber (2008).

Response 1: While the Lorber (2008) model is able to predict perchlorate kinetics for the lactating woman and average adult, it was not developed to predict percent inhibition of radioiodide uptake by perchlorate and does not describe dosimetry in the pregnant mother, fetus, or child. Thus, the PBPK models by Clewell et al. (2007) and Merrill et al. (2005) were chosen to be the most appropriate tool for this analysis.

Comment 2: One reviewer noted that the water intake rates presented in Section 4.3 for 6- to 12-month olds and 1- to 2-year-olds do not appear logical or consistent with the values presented in Kahn and Stralka (2008). The reviewer recommended that they be checked.

Response 2: The reviewer is correct. The values were checked and found to be a typographical error. The values were corrected to reflect those from Table 4 of Kahn and Stralka (2008) that were used in the model.

Subject: Talking points on perchlorate peer review

Jennifer has to speak with Lee this afternoon on the outcome of the perchlorate peer review. Can we draft short (not more than half a page) talking points with a high level summary of what we heard from the peer reviewers?

Perchlorate - Independent Peer Review

- The Perchlorate Peer-Review public meeting took place on January 29 and 30, 2018. Eight panelists provided their feedback on the charge questions the agency charged them regarding the technical soundness of the scientific work developed by EPA.

- Panelists generally appeared impressed with the technical work developed by EPA as the scientific basis to help inform the regulatory decision for Perchlorate in drinking water.

- Stakeholders including: AWWA, Perchlorate Study Group (Via Intertox) and NRDC, provided public comments to the panel during the first day of the meeting.

- Several panelists made suggestions about improvements that could be made to both the BBDR Model and the MCGL approaches that might result in reducing uncertainties and incorporating new statistical metrics. Most panelists appeared to indicate that (based on the available science) the BBDR Modeling approach if far superior in predicting neurodevelopmental outcomes than the RfD approach.

Initial Feedback on BBDR Model:
- Panelists discussed the extent to which the BBDR model parameters should be incorporated into an uncertainty analysis.
- General agreement among panelists that the BBDR model is usable for the setting of an MCLG with moderate confidence in its performance.

Initial Feedback on Two-Stage Approach for informing MCLG:
- EPA has developed a 2-stage approach linking the revised BBDR model results with the quantitative information on neurodevelopmental outcomes from 5 epidemiological studies.
- General agreement among panelists that the second stage of the analysis requires additional consideration of the available data:
    - EPA should attempt to combine data (i.e. meta-analysis) from the positive 5 epidemiological studies if possible.
    - An evaluation of study quality (i.e. bias, sample size, etc.) should be applied to the 5 epi studies (and maybe the Group 2 studies too). This might result fewer studies being used in the stage-2 portion of the analysis.

Initial Feedback on Population-Based Approach for informing MCLG:
- Drs. Leung and Hattis don't like that an adverse cut-point needs to be defined for this approach as there is no such definition of adversity in the clinical setting.
- Dr. Roberts points out that the population-based approach avoids the uncertainties associated with the 5 second-stage epi studies.
- General agreement that this approach would support, but not replace, the 2-stage approach.

Next Steps:
- ORD/NCEA is developing a plan to describe how it intends to respond to the recommendations from the panelists and what is the time frame for completion.
- OGWDW is working with its contractor to outline a plan and schedule for completing necessary revisions to the Draft MCLG Approach Report.
- EPA expects the peer review panel to submit a final Peer Review report outlining all recommendations and responses to EPA's charge by early March.

Good morning,

This email is just a reminder that I am still on the Perchlorate team.

I actually have not received any correspondence emails related to this team activities since Dan Olson's departure.

If I could be included on the meetings and email correspondences related to this team I would appreciate it.

Sincerely,
Jessica

Subject: Public Comment Matrix

Hi Ahmed:
Attached is the most recent draft of all the public comments received. As with the ORD comments we've tried to underline the key comments and label the topic areas to allow for ease in sorting. We have some comments bolded as a carryover from what we did for ORD. However, we have not gone through this whole set of comments and bolded those that we believe are more important. If this is something you would like us to do please let us know, also let us know if there are any questions.

Thanks and have a nice weekend.
Lauren

Subject: BBDR comments

Hi Ahmed:
Attached is the comment matrix we have pulled together for ORD. It includes all the comments we received related to the BBDR model. We've reviewed and **bolded** those that we believe are most important, though I think it would be best if ORD reviewed them all since they have a better understanding of the model and the implications of some of the comments. We have also taken your approach of trying to underline the most important part of the comment to help the reader.

In this matrix we have a "general topic" column which, for this spreadsheet, should almost all be the BBDR model as these were pulled from the larger matrix. We then have the "specific" topic area where one can drill down into the different areas that comments were received on. If you sort alphabetically by this column you should be able to easily group comments which are similar. We also kept in a column of some of our initial thoughts on some of the comments. These only pertain to comments for which we had quick initial responses to – this is has not been done systematically throughout the matrix.

Please let us know if you have questions on this.

Subject: RE: Call in information requested for Perchlorate Charge meeting

Hi Lisa,

I've contacted Versar and have the comments that were submitted to them to include comments from:

- PSG
- AMWA
- DoD
- Intertox
- The Chlorine Institute
- AWWA

I have SBA's comments. I'm unaware of any others from our Federal partners.

I've taken a first pass at the comments and have some thoughts. We can discuss it Monday or whenever is convenient.

Thanks,
Ahmed

All
Let's postpone the meeting until Monday to make sure we have the full set of comments on the charge.
Ahmed can you and/or Greg touch base with Versar to make sure they didn't receive comments we didn't see? There should be comments from DOD, PSG and NASA too
They may also be the in the docket

Thanks so much
Lisa

Subject: Call in information requested for Perchlorate Charge meeting

Good morning Eric,

I apologize for scheduling the meeting without being 100% certain of your availability (and over lunch time).

If it is all right, I would like to amend the invitation with your call in information.

I don't think there's much to discuss unless we received comments other than those from SBA which are the only ones I've seen. We do have a bit of time as the meeting with the Science Advisor is on the 26th, so please suggest a new date/time if one is more convenient to you.

Regards,
Ahmed

Subject: RE: Perchlorate public comment period extension requests - communicating informally to the organizations that requested an extension

Letters are attached

Requesters for extension of just the report comment period by 45 days:
AWWA – request to Mike Shapiro
American Chemistry Council – request to Sam Hernandez

- Thanks for your continued interest in perchlorate in drinking water
- You sent a letter requesting an extension of 45 days of the comment period for the draft report "Proposed Approaches to Inform the Derivation of a Maximum Contaminant Level Goal for Perchlorate in Drinking Water"
- I understand that the BBDR model revisions and analysis in the MCLG Aproaches Report represent complex analysis that require carfeul review.
- I believe that peer review is an important component of the scientific process to assure the use of the best available science, strengthen the interpretation of the reviewed material, and add credibility to the analysis.

- Although I'm not able to extend the public comment period by the full 45 days, EPA can extend it by 21 days – giving reviewers until November 30 to submit comments.
- I believe this will provide adequate time for review and comment while allowing EPA to work to meet deadlines established under the consent decree.

Requesters for extension of both comment periods; 45 days for peer reviewers and charge & 75 days for the report
PSG – request to Mike Shapiro
The Chlorine Institute – request to Sam Hernandez

- Thanks for your continued interest in perchlorate in drinking water
- You sent a letter requesting an extension of 75 days for the comment period for the draft report "Proposed Approaches to Inform the Derivation of a Maximum Contaminant Level Goal for Perchlorate in Drinking Water"
- Your letter also requested a 45 day extension of the public comment period for the draft list of peer reviewers and draft charge
- I understand that the BBDR model revisions and analysis in the MCLG Aproaches Report represent complex analysis that require carfeul review.
- I believe that peer review is an important component of the scientific process to assure the use of the best available science, strengthen the interpretation of the reviewed material, and add credibility to the analysis.
- Unfortunately EPA is not able to extend the comment period for the list of reviewers and the charge, stakeholders have had opportunity for input through the nominations process.
- I can extend the public comment period for the draft MCLG Approaches Report by 21 days.
- I believe this will provide adequate time for review and comment while allowing EPA to work to meet deadlines established under the consent decree.

Subject: RE: Perchlorate public comment period extension requests - communicating informally to the organizations that requested an extension

On Sept 29th, Peter wrote to Mike (see email chain below)

First, we'll appreciate your input on whether we need to seek input from the AO on this approach as well. If we are good to move forward, we would communicate with the organizations that submitted the requests informally, then we'll need to draft formal response letters and quickly put together the FR notices that will be needed to modify the public comment periods. We'll certainly need your help to get these approved quickly.

I am checking in so that we can all be clear on who will informally communicate to the organizations about our response to their request. I am guessing the calls would need to happen this week. My understanding is that the FR notice went upstairs this morning and we expect the FR to be published next week.

I've asked Lisa to draft a few talking points in case Peter is planning to make the calls. We are fine with making the calls if Peter wishes to delegate to SRMD management.

Please let us know.

Take care,

Crystal

Jennifer,

I have an FR template that we used for the last extension so I can draft the new notice. **Please let me know how much time we're are granting for the extension.**

Peter can sign the notice but we need to clear FRNs through OP prior to signature. Mike is out all week and Lee is in the office this Thursday and Friday. He is on travel all next week so this Thursday is our opportunity to have him send an email to clear the FRN through OP and higher. I'll need to end OW the draft FRN and action information sheet by Thursday morning and Macara will request that Lee clear it before he goes on travel next week.

Please let me know if you all can work with the timing.

Thanks,
Steph

Perchlorate Peer Review
Communications Plan

PUBLICATION RELEASE DATE: September 11, 2017

ACTION: The agency is undertaking an independent, external panel peer review and announces the release of scientific materials for public comment that will inform the Safe Drinking Water Act decision making on perchlorate. **KEY MESSAGES**

- Perchlorate – a chemical used in rocket propellants and other applications – may disrupt the normal function of the thyroid gland in both children and adults.
- EPA is currently determining the appropriate scientific approach for understanding the health impacts of exposure to perchlorate in drinking water.
- EPA is conducting a peer review of the draft scientific approach to provide advice to EPA on steps that will yield a highly credible scientific product that is supported by the scientific community.
- EPA will use this peer reviewed science to make future decisions on perchlorate under the Safe Drinking Water Act.
- The agency is releasing the interim list of peer review candidates, draft charge questions as well as a draft scientific report.
- The report provides information regarding how EPA intends to apply BBDR model to inform a quantitative understanding of potential adverse health effects associated with exposure to perchlorate in drinking water.
- The scientific analysis is precedent-setting, therefore EPA is conducting a transparent and rigorous expert peer review process.
- After the peer review is complete, EPA will take the next appropriate steps.

ANTICIPATED REACTION

There is likely to be considerable interest and response to EPA's release of peer review materials and the peer review process itself. Over the past several years, stakeholders have provided extensive comments on publically reviewable perchlorate materials and notices, met with EPA senior officials, managers and staff and have written the Administrator numerous letters.

EPA was sued by NRDC for the Agency's failure to issue proposed and final regulatory actions for perchlorate in accordance with the timelines provided in SDWA. The court approved consent decree established a schedule for completing the peer review process (10/18/17) and signature of a proposed (10/31/18) and final rule (12/19/19).

Stakeholders and the press are aware that EPA has been working to implement SAB recommendations and develop a BBDR model and scientific approach to inform decisions on perchlorate.

Stakeholder response will generally be critical of the highly technical, underlying science to model perchlorate in sensitive lifestages and the novel application of the model output to inform an understanding of the health impacts of exposure to perchlorate in drinking water.

- Industry groups (Perchlorate Study Group, American Chemistry Council); drinking water utilities, the U.S. Chamber of Commerce and the Department of Defense will likely be critical of the underlying science
- Environmental groups will likely be critical of the underlying science.
- Consumers, both those using public water systems and private wells, will be concerned about potential health risks from perchlorate.

Perchlorate Peer Review
Communications Plan

DESK STATEMENT

Ensuring the safety of drinking water for all Americans is a top priority for EPA. The agency has initiated a peer review and is releasing scientific materials that inform decision making on perchlorate under the Safe Drinking Water Act. The materials include an interim list of peer review candidates, draft charge questions as well as a detailed report describing the biologically based dose-response model EPA developed and information regarding how EPA intends to apply modeling to understand the health impacts of exposure to perchlorate in drinking water. After the peer review is complete, EPA will take the next appropriate steps on perchlorate under the Safe Drinking Water Act.

Background

On January 8, 2009, EPA released an interim drinking water health advisory of 15 parts of perchlorate for every billion parts of water (parts per billion or ppb). This level was determined using a reference based dose response based on the recommendation of the National Research Council (NRC).

In 2011, EPA announced its decision (76 FR 7762) to regulate perchlorate under the Safe Drinking Water Act (SDWA). In accordance with SDWA, the Agency requested EPA's Science Advisory Board (SAB) to review how to consider available data in deriving a Maximum Contaminant Level Goal (MCLG) for use in developing a perchlorate National Primary Drinking Water Regulation. The MCLG is a non-enforceable goal defined under the SDWA as "the level at which no known or anticipated adverse effects on the health of persons occur and which allows an adequate margin of safety." The MCLG is one of the considerations in developing the enforceable maximum contaminant level (MCL) for a regulated contaminant. The SAB released its final report on May 29, 2013 and recommended that EPA "derive a perchlorate MCLG that addresses sensitive life stages through physiologically-based pharmacokinetic/pharmacodynamic (PBPK/PD) modeling."

In response to the Science Advisory Board's recommendations, the Office of Water worked with scientists from the Office of Research and Development and the Food and Drug Administration to develop a biologically based dose-response (BBDR) model that accounts for population differences in iodide exposure and predicts changes in thyroid hormone levels that result from exposure to perchlorate. We also assessed epidemiology studies that link thyroid hormone changes to developmental effects. EPA completeda peer review of the BBDR model and the report provided by the reviewers can be found on EPA's website at:
https://www.epa.gov/dwstandardsregulations/perchlorate-drinking-water.

Legal Deadlines: On February 18, 2016, the Natural Resource Defense Council filed a complaint for the Southern District of N.Y., alleging that EPA failed to perform a nondiscretionary duty under SDWA to propose and finalize a national primary drinking water regulation for perchlorate. On October 18, 2016, the court approved a consent decree establishing dates for –

- completing the peer review process (10/18/17, non-enforceable);
- filing a peer review status report (10/30/17); and
- signature of a proposed and final rule (10/31/18 and 12/19/19, respectively).

Perchlorate Peer Review
Communications Plan

COMMUNICATIONS MATERIALS

Webpage (link will appear on https://www.epa.gov/dwstandardsregulations/perchlorate) will include:

- Link to public inspection FR notice
- Draft Charge Questions
- Interim List of Peer Reviewers
- Draft scientific report on the application of the model to inform decisions on perchlorate

RELEASE SCHEDULE

-3 days

- OGWDW/SRMD notification of Regional Contacts
- OPA notification of Regional PADS

-2 days

- SRMD notification of federal partners (FDA, ATSDR, NIEHS, OMB)
- OPA calls to federal agencies' communications

Release Day (when publically available on FR site)

9:00 a.m	Begin head's up calls to stakeholder list below
10:00 a.m	Congressional heads up emails
12:00 p.m	Website goes live – Broader congressional notifications (emails with link to website).
1:00 p.m	Social media and stakeholder notification via email (Water Headlines listserv)

STAKEHOLDER NOTIFICATION

OGWDW:

- Michael Deane, Director, National Association of Water Companies
- Tracy Mehan, Government Affairs Director, American Water Works Association
- Mike Paque, Executive Director, Groundwater Protection Council
- Alan Roberson, Executive Director, Association of State Drinking Water Administrators
- Lynn Thorp, National Campaigns Director, Clean Water Action
- Diane Van de Hei, Executive Director, Association of Metropolitan Water Agencies
- Sam Wade, Executive Director, National Rural Water Association
- Nathan Ohle, Executive Director, Rural Community Assistance Partnership
- Tom Neltner, Chemicals Policy Director, Environmental Defense Fund
- Alexandra Dapolito Dunn, The Environmental Council of States

OGC:

- Eric Olson/Mae Wu, Natural Resources Defense Council

OLEM (OSRTI):

- Association of State and Territorial Solid Waste Management Officials

Perchlorate Peer Review
Communications Plan

EXTERNAL QUESTIONS AND ANSWERS

CONSUMER QUESTIONS

Where is perchlorate found?
Perchlorate occurs naturally in arid states in the Southwest United States, in nitrate fertilizer deposits in Chile, and in potash ore in the United States and Canada. It also forms naturally in the atmosphere. Perchlorate is manufactured and used as an industrial chemical and can be found in rocket propellant, explosives, fireworks and road flares. It has been found in some public drinking water systems and in food.

Why is perchlorate in drinking water a health concern?
Perchlorate may disrupt the normal function of the thyroid gland in both children and adults. In adults, the thyroid plays an important role in metabolism, making and storing hormones that help regulate the heart rate, blood pressure, body temperature, and the rate at which food is converted into energy. In fetuses and infants, thyroid hormones are critical for normal growth and development of the central nervous system. Perchlorate can interfere with the human body's ability to absorb iodine into the thyroid gland which is a critical element in the production of thyroid hormones.

How does perchlorate get into my drinking water?
Perchlorate is dissolves easily, is relatively stable and is mobile in water. While it has often been detected in water supplies in close proximity to sites where solid rocket fuel is manufactured or used, there are also many locations in the United States lacking a clearly defined source.

Besides drinking water, how else can people be exposed to perchlorate?
People are exposed to perchlorate primarily through eating contaminated food or drinking water. The Food and Drug Administration (FDA) Total Diet Study combines nationwide sampling and analysis of hundreds of food items along with national surveys of food intake to develop comprehensive dietary exposure estimates for a variety of demographic groups in the U.S. In the 2008-2012 survey the FDA found detectable levels of perchlorate in 97 percent of the foods sampled. The complete set of FDA perchlorate data can be found here:
[HYPERLINK "https://www.fda.gov/Food/FoodborneIllnessContaminants/ChemicalContaminants/ucm077615.htm"]

Have public drinking water systems been sampled for perchlorate?
Customers served by a public water system can contact their local water supplier and ask if they test for perchlorate. If so, they are encouraged to obtain a copy of their Consumer Confidence Report. This report lists the levels of contaminants that have been detected in the water, including those tested by EPA, and whether the system meets state standards or guidelines. If you are concerned about the possibility of perchlorate in your drinking water and you are served by a private well, EPA recommends testing your drinking water. In addition, EPA recommends that residents reach out to their local public health department for more information on testing your water.

The most recent Consumer Confidence Report can be obtained from your drinking water utility, by visiting their website or contacting them for a copy. Some public water systems upload their Consumer

Confidence Report to EPA's website at: [HYPERLINK "http://www.epa.gov/ccr" \h]. Information about private wells can be found here: [HYPERLINK "http://www.epa.gov/privatewells" \h].

Also, if your public water system participated in collecting monitoring data for UCMR 1, you can find information about your system at: [HYPERLINK "https://www.epa.gov/dwucmr/first-unregulated-contaminant-monitoring-rule"].

I live in a community with elevated perchlorate levels. Who do I call to get more information about what my utility is doing to address the elevated levels?
Contact your local water supplier to find out more about perchlorate in your drinking water. If you don't know who your local water supplier is, the information should be included in your latest water bill.

I get my tap water from a private well. How can I find out if perchlorate are in my water?
If you are concerned about the possibility of perchlorate in your drinking water and you are served by a private well, EPA recommends testing your drinking water. Approved laboratories can analyze a sample of your water to determine whether perchlorates are present and at what concentrations. Your local water or health department or drinking water system should know if there is such a program in your area. In addition, EPA recommends that residents reach out to their local public health department or state who may be able to help provide support for testing or to seek such support from a responsible party. If no program has been established or support is not available in your area, you can pay to have independent testing done at a qualified testing lab (typical cost is several hundred dollars per sample).

More information about private wells can be found here: [HYPERLINK "http://www.epa.gov/privatewells" \h].

Can a person drink tap water containing perchlorate at or below the level of the health advisory every day of their life and not expect adverse health effects from these chemicals?
Yes, the EPA health advisory level offers a margin of protection for all Americans from adverse health effects for a lifetime of exposure to perchlorate in drinking water at 15ppb.

Can perchlorate be boiled out of my water?
No, perchlorate cannot be removed by heating or boiling water.

Should I be worried about reconstituting my child's infant formula with tap water?
Refer to FDA

Should I consider taking iodine dietary supplements if I am worried about perchlorate?
Refer to FDA

How does a utility reduce/remove perchlorate?
A number of options are available to drinking water systems to lower concentrations of perchlorate in the drinking water supply. In some cases, drinking water systems may be able to reduce concentrations of perchlorate by closing contaminated wells or changing rates of blending of water sources. Perchlorate can be removed using a number of advanced treatment techniques. Each technique has advantages and disadvantages depending on the level of perchlorate present in the source water, removal goals, other water quality parameters, competing treatment objectives, and treatment waste

disposal options. Regenerable and single-pass ion exchange, reverse osmosis, and fixed- and fluidized-bed biological treatment can all remove perchlorate from drinking water sources.

These treatment systems are used by some public water systems today, but should be carefully designed and maintained to ensure that they are effective for treating perchlorate.

Home drinking water treatment units are typically certified by independent third party organizations against ANSI (American National Standards Institute) standards to verify their contaminant removal claims. Some home filters remove impurities using reverse osmosis; however, there currently are no ANSI protocols for testing home treatment systems to verify that these devices effectively remove perchlorate or how frequently the filters should be changed in order to maintain removal efficiency.

Can I buy a home treatment device to remove perchlorate?
If you are concerned about perchlorate in your drinking water, you may consider purchasing a home treatment device such as a filter. However, in order to make a well-informed and cost-effective decision, consider checking with your water system or consumer confidence report to learn about the amount of total perchlorate in your water and identifying a device that has been independently certified to remove perchlorate.

[HYPERLINK "http://www.nsf.org/consumer-resources/what-is-nsf-certification/water-filters-treatment-certification/contaminant-reduction-claims-guide" \t "_blank"], the [HYPERLINK "https://www.wqa.org/" \t "_blank"], [HYPERLINK "http://ul.com/" \t "_blank"] and [HYPERLINK "http://www.csagroup.org/global/en/services/testing-and-certification" \t "_blank"] all certify home treatment products for removal of contaminants. The relevant perchlorate removal standard is [HYPERLINK "http://www.nsf.org/consumer-resources/health-and-safety-tips/water-quality-treatment-tips/standards-for-water-treatment-systems" \t "_blank"]. If you choose to use a home treatment device, it is very important to follow the manufacturer's operation and maintenance instructions carefully in order to make sure the device works properly.

Does perchlorate have a health advisory level?
Yes, on January 8, 2009, EPA released an interim drinking water health advisory of 15 parts of perchlorate for every billion parts of water (parts per billion or ppb). For more information on the Interim Drinking Water Health Advisory for perchlorate can be found here: [HYPERLINK "http://nepis.epa.gov/Exe/ZyPURL.cgi?Dockey=P1004X7Q.txt"]

Has a safe level of exposure for perchlorate been established?
On February 11, 2011, EPA determined that perchlorate meets the Safe Drinking Water Act criteria for regulation as a contaminant. The Agency found that perchlorate may have an adverse effect on the health of persons and is known to occur in public drinking water systems with a frequency and at levels that present a public health concern. Since that time, EPA has been reviewing the best available scientific data on a range of issues related to perchlorate in drinking water including its occurrence, treatment technologies, analytical methods and the costs and benefits of potential standards.

There also have been state actions on perchlorate standards, guidelines, and advisories. In 2006, Massachusetts adopted a drinking water standard for perchlorate of 2 µg/L, and in 2007, California promulgated a standard of 6 µg/L. Twelve other states have established non-enforceable guidance

levels, action or advisory levels. Depending on the state, a particular level may require a public water system to notify the public, serve as a screening tool for further action, or guide clean-up actions.

Customers that are served by a public water system can contact their local water supplier and ask for information on perchlorate in their drinking water, and are encouraged to request a copy of their Consumer Confidence Report. This report lists the levels of contaminants that have been detected in the water, including those by EPA, and whether the system meets state and EPA drinking water standards.

PEER REVIEW QUESTIONS

Why is EPA conducting a peer review?
EPA will ask peer reviewers to comment on products that the agency will use to inform decision making on perchlorate under the Safe Drinking Water Act

EPA believes that peer review is an important component of the scientific process. The critical feedback, suggestions, and new ideas provided by the peer reviewers stimulate creative thought, strengthen the interpretation of the reviewed material, and confer credibility on the product. The peer review objective is to provide advice to EPA on steps that will yield a highly credible scientific product that is supported by the scientific community.

What products will be reviewed?
Peer reviewers will be asked to comment on the draft report entitled "Peer Review Draft: Proposed Approach to Inform the Derivation of a Maximum Contaminant Level Goal for Perchlorate in Drinking Water." Additionally, EPA is seeking public comments on the peer review charge and the interim list of expert peer review panel candidates.

Where can I find the review products?
All documents in the docket are listed on the [HYPERLINK "http://www.regulations.gov"] website under Docket ID Numbers EPA-HQ-OW-2016-0438 and EPA-HQ-OW-2016-0439.

Can I provide comments on the review products?
Yes. The public will have an opportunity to review and comment on the draft charge questions, the interim list of peer reviewers and the draft report describing application of the model to inform decision making on perchlorate in drinking water.

Additionally, we intend to allow for people to make brief statements during the meeting, and any Safe Drinking Water Act decisions on perchlorate will be subject to public notice and comment.

How long is the comment period?
EPA announced that it's seeking public comments on two separate sets of materials. The first set is the interim list of peer review candidates and the draft charge questions. People should send their comments to Versar, Inc. no later than 21 days after publication in the Federal Register.

A companion notice, also published on the same date, requests comments on the draft scientific report on application of the model to inform decision making on perchlorate. People should send their comments to the docket no later than 45 days after publication in the Federal Register.

Perchlorate Peer Review
Communications Plan

Will the review panelists see my comments or just EPA?
EPA will provide panelists a summary of the public comments submitted on the draft products.

When and where will EPA hold the meeting?
The meeting is projected to occur during in the late fall of 2017 (exact date to be determined). EPA will announce the meeting in the Federal Register at least 30 days in advance to provide the meeting date, location and registration information. EPA anticipates holding the two-day meeting in the Washington, DC metro area.

What will EPA do with the public comments and panel recommendations?
A peer review summary report will be developed that contains the full final comments and recommendations from the peer reviewers. EPA will make the final peer review report available to the public.

EPA will consider any public comments and peer reviewer comments submitted in accordance with the Federal Register notice when finalizing the documents.

How will the contractor select the reviewers?
The contractor considered and screened all candidates against the selection criteria described in the March 1, 2016, and June 3, 2016, Federal Register notices (81 FR 10617 and 81 FR 35760, respectively) which included being free of any conflict of interest and being available to participate in-person in the peer review meeting.

Following the screening process, the list was narrowed to 12 candidates. EPA is now soliciting comments on the interim list of 12 candidates. Once the public comments on the interim list of candidates have been reviewed and considered, and the Science Integrity Official has been consulted, the final list of peer reviewers will be selected.

What happens next?
Once the public comments on the interim list of candidates have been reviewed and considered, the final list of peer reviewers will be selected.

What happens after the peer reviewers are selected?
Following the selection process, the peer reviewers will be tasked with evaluating and providing written comments on the draft products. Additionally, peer reviewers will be provided a summary of public comments and will be provided with the full set of public comments submitted during the draft document's public comment period.

When will EPA establish a national drinking water standard for perchlorate?
EPA will to consider public comments and peer reviewer comments submitted in accordance with the Federal Register notice when finalizing the peer review products. After the peer review is complete, EPA will take the next appropriate steps.

Why is it taking so long for EPA to regulate perchlorate?
In 2011, EPA announced its decision to regulate perchlorate under the Safe Drinking Water Act (SDWA).

Perchlorate Peer Review
Communications Plan

In accordance with SDWA, the Agency requested EPA's Science Advisory Board (SAB) to review how to consider available data in deriving a Maximum Contaminant Level Goal (MCLG) for use in developing a perchlorate National Primary Drinking Water Regulation. The SAB released its final report on May 29, 2013 and recommended that EPA use a novel scientific modeling approach.

The agency, with contributions from Food and Drug Administration scientists, spent over three years to develop the model that predicts changes in thyroid hormone levels that result from exposure to perchlorate. We also assessed epidemiology studies that link thyroid hormone changes to developmental effects. EPA convened a peer review panel to provide recommendations on the model in January 2017 and revised the model considering the comments received in the peer review report submitted to the agency on March 29, 2017. EPA is now initiating the second stage of peer review on scientific materials to support decision making on perchlorate.

INTERNAL QUESTIONS AND ANSWERS

What is the status of the NRDC complaint
On February 18, 2016, the Natural Resource Defense Council filed a complaint in the United States District Court for the Southern District of N.Y. alleging that EPA failed to perform a nondiscretionary duty under SDWA to propose and finalize a national primary drinking water regulation for perchlorate. On October 18, 2016, the court approved a consent decree establishing dates for –

- completing the peer review process (10/18/17, non-enforceable);
- if peer review not complete by 10/18/2017, filing a peer review status report (10/30/17); and
- signature of a proposed and final rule (10/31/18 and 12/19/19, respectively).

Will the peer review products present alternative MCLGs?
No, the documents will not present alternative MCLGs. The documents present various scientific approaches for understanding the potential health impacts from exposure to perchlorate in drinking water. However some experts can be expected to use the scientific methodologies described in the report to speculate how the Agency may derive an MCLG.

Will the methodologies that will be presented to the peer reviewers result in MCLGs that are in the range of MCLs set by California (6 µg/L) and Massachusetts (2 µg/L)?
We do not yet know. The draft analysis could result in values higher than currently used. However, the upcoming peer review of the scientific assessment is an important factor in our understanding of the science.

What is our evaluation of perchlorate occurrence data?

The UCMR 1 perchlorate dataset is the best available nationally representative data on perchlorate occurrence in public water systems. Analytical detections of perchlorate at or above the minimum reporting level (4 µg/L) were identified in about 4% (155 of 3,865) of these systems. EPA estimates that between 5.1 million to 16.6 million people served by the sampled systems could be exposed to perchlorate in drinking water. While perchlorate analytical detections are fairly numerous and widespread geographically, the UCMR 1 findings indicate that perchlorate occurs at relatively low levels: about 85% of analytical perchlorate detections are less than 13 µg/L and 42% are less than 6 µg/L.

However, commenters have pointed out limitations of UCMR 1 for estimating current occurrence. The minimum reporting level is 4 µg/L. Since UCMR 1 data has been collected 2 states have enacted perchlorate standards (CA & MA) and remediation activities or new sources of perchlorate may have impacted concentration levels in public water systems.

Are there any cross-office implications of promulgating a drinking water regulation?
Yes, a drinking water regulation for perchlorate would become the applicable or relevant and appropriate requirement (ARAR) and would replace the current preliminary remediation goal (PRG) for CERCLA sites (current PRG is based on the Interim Drinking Water Health Advisory level of 15 µg/L).

Is there an Environmental Justice/Equity component for the affected communities?
Each community faces unique challenges when addressing concerns related to environmental issues. Perchlorates in drinking water are related to localized sources of contamination often near where these produced have been manufactured or produced. Currently, if water sampling results confirm that drinking water contains perchlorate at individual or combined concentrations greater than 15 parts per billion, water systems should undertake additional sampling to assess the level, scope and localized source of contamination to inform next steps.

How will the RfD, or the interim health advisory, be used to inform the MCLG?
Based on SAB recommendations EPA does not intend to use the perchlorate RfD to inform derivation of an MCLG. The SAB stated that it, ". . . recognizes that this is a novel approach as compared to previous MCLG derivations that use the RfD and exposure factors. However, PBPK/PDIUI modeling provides a more rigorous tool to integrate the totality of information available on perchlorate, and this approach may better address different life stage susceptibilities to perchlorate than the default MCLG approach."

Hi Lisa and Crystal,

Jennifer got back to me with the Perchlorate Roll-out plan comments. One question remaining she had is if you can add all the stakeholders and federal partners that participated in the meetings thus far to the list. OW Comms needs this by noon.

Also if Mike approves the 09/11 date, we will need to notify our stakeholders tomorrow. I will coordinate up with here with Peter and Jennifer but will likely copy you both on these as I do not want to duplicate efforts.

Thanks so much.

Sincerely,

Marisa Tricas

Hi, Lisa!

Hope you are well. Nicole sent me this email today asking me if I knew someone from TAB, specifically from the perchlorate team, that might be interested in doing a policy review. I asked Ahmed if he was interested. Do you have someone else in mind? Thanks in advance!

Hi Alia,
Hope you are doing well. Ryan Albert has asked me to coordinate with appropriate TAB person for this manuscript, to ask them to review. The manuscript is about endocrine disruptors that disrupt the thyroid.
In the fact sheet for the manuscript it mentions "Monovalent anions, such as the environmental contaminant perchlorate, have been well characterized as competitive inhibitors of NIS-mediated uptake of iodide, but limited information exists for more structurally diverse chemicals."
I am thinking someone from the perchlorate team would be best suited to review. ORD is looking for a policy review, but if someone has other comments that could provide those as well if they wanted.
Do you have a person in mind that would be best suited to review this manuscript that I could ask? Thanks Alia.

I think this paper mostly related to SRRB's oversight of the agency's Endocrine Disruptor Screening Program. However, TAB should be aware of this high throughput screening in the context of future CCLs.

SRRB, please take the lead in reviewing the paper. For others, if your unit plans to also review, please let SRRB know so they can expect to receive your comments before the deadline. Thanks.

Abstract. The U.S. EPA's Endocrine Disruptor Screening Program (EDSP) and Office of Research and Development (ORD) are currently developing high throughput assays to screen chemicals that may alter the thyroid hormone pathway. One potential target in this pathway is the sodium iodide symporter (NIS), a transmembrane glycoprotein that mediates iodide uptake into the thyroid gland as the initial step in thyroid hormone biosynthesis. Our laboratory recently validated a screening approach to identify potential NIS inhibitors using a novel cell line hNIS-HEK293T-EPA. Here, we screened the ToxCast phase 1_v2 chemical library, representing 293 unique environmental chemicals, in the newly developed radioactive iodide uptake (RAIU) assay. First, 310 blinded samples were screened in single-concentration format at 100μM. Using 20% inhibition as the activity threshold, 169 samples reached this criterion and were further tested for concentration-response (0.001 μM - 100 μM) with parallel RAIU and cell viability assays. To facilitate prioritization of potential thyroid toxicants, a unique ranking system that incorporates cytotoxicity responses was developed to sort the RAIU inhibition potency of the chemicals. Chemicals were ranked with a score that is relative to

the well-known NIS inhibitor sodium perchlorate. The top ranked 14 chemicals had varying responses in the screening and their diverse toxicological properties are discussed in detail. Further testing is warranted to characterize the nature of the inhibition observed with these chemicals. This study represents the first large-scale screening of environmental chemicals for NIS inhibitors, and supports the U.S. EPA's EDSP21 and OECD in their efforts to develop high throughput screening approaches that expand the coverage of molecular targets of thyroid disruption.

Subject: ADVANCE NOTIFICATION -- ORD-023135 Wang et al. Screening of ToxCast Phase I Chemicals in the NIS Assay (Iodide transport)

Good morning:
ORD is providing advanced notification of a recently developed manuscript entitled: ***High-Throughput Screening of ToxCast Phase I Chemical Library for Sodium Iodide Symporter (NIS) Inhibitors*** by Wang, et al. This paper presents a novel *in vitro* screening approach that was developed to rapidly identify chemicals that can inhibit the uptake of iodide by the thyroid and disrupt the synthesis of thyroid hormones. The assay targets a key molecular initiating event, the uptake of iodide as mediated by the thyroid sodium iodide symporter (NIS), within the thyroid hormone pathway. This assay was used to screen the ToxCast Phase 1 chemical library.

The screening and ranking of 293 chemicals in this study represents the first large scale effort to investigate NIS as a molecular target of environmental chemicals that covers a broad spectrum of structural and toxicological properties. This assay and ranking approach can now be used for screening other, larger chemical libraries such as the ToxCast Phase 2 and E1K libraries.

The goal of this advanced notification is to provide our colleagues a heads-up concerning important ORD products so as avoid any surprises and to provide you the opportunity to review products for policy relevant concerns. **We ask for your comments by COB September 19.**

Please provide any comments you might have to Jeff Frithsen. Meanwhile, if you have questions, please contact me.
Thank you!
Joe

Abstract

The U.S. EPA's Endocrine Disruptor Screening Program (EDSP) and Office of Research and Development (ORD) are currently developing high throughput assays to screen chemicals that may alter the thyroid hormone pathway. One potential target in this pathway is the sodium iodide symporter (NIS), a transmembrane glycoprotein that mediates iodide uptake into the thyroid gland as the initial step in thyroid hormone biosynthesis. Our laboratory recently validated a screening approach to identify potential NIS inhibitors using a novel cell line hNIS-HEK293T-EPA. Here, we screened the ToxCast phase 1_v2 chemical library, representing 293 unique environmental chemicals, in the newly developed radioactive iodide uptake (RAIU) assay. First, 310 blinded samples were screened in single-concentration format at 100μM. Using 20% inhibition as the activity threshold, 169 samples reached this criterion and were further tested for concentration-response (0.001 μM - 100 μM) with parallel RAIU and cell viability assays. To facilitate prioritization of potential thyroid toxicants, a unique ranking system that incorporates cytotoxicity responses was developed to sort the RAIU inhibition potency of the chemicals. Chemicals were ranked with a score that is relative to the well-known NIS inhibitor sodium perchlorate. The top ranked 14 chemicals had varying responses in the screening and their diverse toxicological properties are discussed in detail. Further testing is warranted to characterize the nature of the inhibition observed with these chemicals. This study represents the first large-scale screening of environmental chemicals for NIS inhibitors, and supports the U.S. EPA's EDSP21 and OECD in their efforts to develop high throughput screening approaches that expand the coverage of molecular targets of thyroid disruption.

Keywords: sodium iodide symporter, thyroid, endocrine disruptor, high-throughput *in vitro* screening assay

Introduction

Thyroid hormones (TH; i.e., thyroxine (T4) and triiodothyronine (T3)) regulate an array of physiological processes that are essential for metabolism, cardiovascular function, bone maintenance, as well as fetal and post-natal neurodevelopment [ADDIN EN.CITE ADDIN EN.CITE.DATA]. Over the past two decades, a number of structurally diverse xenobiotics have been shown to interfere with TH homeostasis and result in physiological and morphological perturbations [ADDIN EN.CITE ADDIN EN.CITE.DATA]. Further work in this area has identified multiple molecular targets of chemical-mediated thyroid disruption including the regulation of circulating TH through feedback mechanisms within the hypothalamic-pituitary-thyroid (HPT) axis, TH synthesis and secretion, TH distribution and transport, TH metabolism, and TH receptor binding and action [ADDIN EN.CITE ADDIN EN.CITE.DATA]. These studies demonstrated a need for a better understanding of the structural characteristics of chemicals with thyroid disrupting activity, the potential for environmental exposures, and the possible health risks to humans and wildlife. To address these concerns, the U.S. EPA's Endocrine Disruptor Screening Program (EDSP21, https://www.epa.gov/endocrine-disruption) in concert with the U.S. EPA's Office of Research and Development (ORD) recently expanded the coverage of molecular targets for disruption of the TH pathway by developing and implementing the use of high throughput screening (HTS) assays to identify inhibitors of TH synthesis (e.g., sodium/iodide symporter (NIS) and thyroid peroxidase) and T4 metabolism (e.g., deiodinases). Methods for a thyroid peroxidase assay were previously described by Paul et al. (2014) and used to screen chemicals in the ToxCast phase I_v2 and II chemical libraries [ADDIN EN.CITE

NIS is a glycoprotein with 13 transmembrane helices [ADDIN EN.CITE ADDIN EN.CITE.DATA] that actively transports I^- anions into thyroid follicular cells. This activity relies on the inwardly directed Na^+ electrochemical gradient maintained by Na^+/K^+ ATPases with an electrogenic stoichiometry of 2 Na^+ per I^- [ADDIN EN.CITE ADDIN EN.CITE.DATA]. Under normal physiological conditions, NIS can efficiently enrich iodide into the thyroid gland to achieve a 20 to 40 fold I^- concentration gradient [ADDIN EN.CITE <EndNote><Cite><Author>Dohán</Author><Year>2003</Year><RecNum>5</RecNum><DisplayText>(Dohán<style face="italic"> et al.</style>, 2003)</DisplayText><record><rec-number>5</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1493133346">5</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Dohán, Orsolya</author><author>De la Vieja, Antonio</author><author>Paroder, Viktoriya</author><author>Riedel, Claudia</author><author>Artani, Mona</author><author>Reed, Mia</author><author>Ginter, Christopher S.</author><author>Carrasco, Nancy</author></authors></contributors><titles><title>The Sodium/Iodide Symporter (NIS): Characterization, Regulation, and Medical Significance</title><secondary-title>Endocrine Reviews</secondary-title></titles><periodical><full-title>Endocrine Reviews</full-title></periodical><pages>48-77</pages><volume>24</volume><number>1</number><dates><year>2003</year></dates><i

Apart from the thyroid gland, NIS is also expressed in other tissues such as mammary gland during lactation, stomach, and salivary gland [ADDIN EN.CITE ADDIN EN.CITE.DATA]. Disruption of NIS-mediated iodide uptake has been correlated with depressed TH synthesis (hypothyroidism) and adverse health outcomes in humans and animals. For example, patients with various gene mutations leading to aberrant NIS protein have hypothyroidism [ADDIN EN.CITE <EndNote><Cite><Author>Pohlenz</Author><Year>1999</Year><RecNum>97</RecNum><DisplayText>(Pohlenz and Refetoff, 1999)</DisplayText><record><rec-number>97</rec-number><foreign-keys><key app="EN" db-id="tsarvxesktrfvwe9d9rxsxthda0dev5r55ef" timestamp="1494530226">97</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Pohlenz, Joachim</author><author>Refetoff, Samuel</author></authors></contributors><titles><title>Mutations in the sodium/iodide symporter (NIS) gene as a cause for iodide transport defects and congenital hypothyroidism</title><secondary-title>Biochimie</secondary-title></titles><periodical><full-title>Biochimie</full-title></periodical><pages>469-476</pages><volume>81</volume><number>5</number><keywords><keyword>congenital hypothyroidism</keyword><keyword>thyroid</keyword><keyword>iodide transport</keyword><keyword>molecular genetics</keyword></keywords><dates><year>1999</year><pub-dates><date>5//</date></pub-dates></dates><isbn>0300-9084</isbn><urls><related-

In addition, several monovalent anions including perchlorate (ClO_4^-), thiocyanate (SCN^-), and nitrate (NO_3^-) are known to competitively inhibit I^- uptake by NIS and disrupt TH synthesis in humans [ADDIN EN.CITE ADDIN EN.CITE.DATA] and multiple species of vertebrates [ADDIN EN.CITE ADDIN EN.CITE.DATA]. The identification of the environmental chemicals triclosan, triclocarban, BDE-47, bisphenol A (Wu *et al.*, 2016), and several small drug-like organic molecules as NIS-mediated iodide transport inhibitors [ADDIN EN.CITE ADDIN EN.CITE.DATA] indicates effects on NIS that extend beyond simple competitive inhibition by anions.

We recently developed a radioactive iodide uptake (RAIU) assay to measure uptake of iodide in a novel cell line stably expressing human sodium/iodide symporter, hNIS-HEK293T-EPA [ADDIN EN.CITE

urls></urls><electronic-resource-num>10.1021/acs.chemrestox.6b00135</electronic-resource-num></record></Cite></EndNote>], as well as a subset of chemicals that have been tested extensively in the Agency's EDSP Tier I Screening Battery [ADDIN EN.CITE <EndNote><Cite><Author>U.S.EPA</Author><Year>2015</Year><RecNum>111</RecNum><DisplayText>(U.S.EPA, 2015)</DisplayText><record><rec-number>111</rec-number><foreign-keys><key app="EN" db-id="tsarvxesktrfvwe9d9rxsxthda0dev5r55ef" timestamp="1499365200">111</key></foreign-keys><ref-type name="Online Database">45</ref-type><contributors><authors><author>U.S.EPA</author></authors></contributors><titles><title>Endocrine Disruptor Screening Program Tier 1 screening determinations or weight of evidence assessments.</title></titles><dates><year>2015</year><pub-dates><date>July 6, 2017</date></pub-dates></dates><pub-location>https://www.epa.gov/endocrine-disruption/endocrine-disruptor-screening-program-tier-1-screening-determinations-and</pub-location><urls><related-urls><url>https://www.epa.gov/endocrine-disruption/endocrine-disruptor-screening-program-tier-1-screening-determinations-and</url></related-urls></urls></record></Cite></EndNote>]. This study expands the current knowledge of NIS inhibition potential of environmentally-relevant chemicals and the results may be used for prioritizing chemicals for further testing and informing the development of adverse outcome pathways for thyroid disruption.

Materials and Methods

Cell Line and Growth Conditions

As described by Hallinger et al. (2017), an HEK293T cell line expressing functional human NIS, hNIS-HEK293T-EPA, was utilized for radioactive iodide uptake (RAIU) and cell viability assays. In brief, low passage hNIS-HEK293T-EPA cells (<30 passes) were cultured in Dulbecco's Modified Eagle Medium (DMEM; Gibco,Waltham, MA) supplemented with 10% newborn calf serum (Gibco, Waltham, MA), 10mM HEPES, 100U/mL penicillin and 0.1mg/mL streptomycin (Sigma, St. Louis, MO) at 37°C in a humidified 5% CO_2 atmosphere. Culture flasks were coated with collagen type I (Corning, Corning, NY) in 0.02N acetic acid solution (4µg per cm^2) and washed with sterile deionized H_2O prior to subculture. All 96-well microplates were coated with 0.01% poly-L-lysine (Sigma, St. Louis, MO) and washed with sterile deionized H_2O prior to cell seeding. Cells were grown to 90 – 95% confluence in T75 flasks (Corning, Corning, NY) before trypsinization in 0.05% trypsin/EDTA (Gibco, Waltham, MA) where cells were sub-cultured in T75 flasks or seeded in 96-well plates as described in assay sections below.

Chemicals

Chemical names, CAS numbers, and maximum concentration tested are shown in Tables 1 (Assay controls) and 2 (Test chemicals). All control chemicals were initially solubilized in DMSO (EMD Millipore Corp., Darmstadt, Germany) at 20 mM and included sodium perchlorate ($NaClO_4$; RAIU assay positive control), sodium nitrate ($NaNO_3$; RAIU assay EC_{80} control), sodium thiocyanate

(NaSCN; RAIU assay EC_{20} control), 2,4-dichlorophenoxyacetic acid (2,4-D; RAIU assay negative control), and 2,3-dichloro-1,4-napthoquinone (DCNQ; cell viability assay positive) (Sigma Aldrich, St. Louis, MO).

Chemicals of the ToxCast phase 1_v2 library were solubilized in DMSO and provided as 310 blinded samples in five 96-well plates (62 samples per plate) (Evotec Inc., South San Francisco, CA). Of the 310 samples, there were 293 unique chemicals - the remaining 17 serving as internal quality control replicates randomly distributed among the five plates. All chemicals were administered to bioassay plates using a BioMek FX Automated Laboratory Workstation (Beckman Coulter, Indianapolis, IN) equipped with a stainless steel high density replicating (HDR) tool (96-pin) to transport 350nL per well for the RAIU, cell viability, and Sandell-Kolthoff (SK) assays as described below.

Radioactive Iodide Uptake (RAIU) Assay

RAIU assays were conducted as previously described (Hallinger *et al.* 2017). In brief, hNIS-HEK293T-EPA cells were seeded with a MultiFlo FX dispenser (BioTek, Winooski, VT) into ScintiPlate-96 microplates (Perkin Elmer, Waltham, MA) at a density of $4.0x10^4$ cells per well in 200µL growth media and incubated for 40 hours before experimentation. On the day of the assay, carrier-free ^{125}I (Perkin-Elmer, Waltham, MA; specific activity: 17.4Ci/mg) was diluted with Hanks' balanced salt solution (Sigma, St. Louis, MO) supplemented with 10mM HEPES (uptake buffer; pH 7.4) at 5µCi/mL (288pg ^{125}I/mL uptake buffer; 2.30nM). The assay was initiated by gently washing cells twice with 200µL uptake buffer using a 96-well Tecan HydroSpeed plate

washer (Tecan, Männedorf, Switzerland). Uptake buffer (59.7µL) was then added back to each well. Chemical samples (350nL at 200X) were added to each well using the HDR tool as previously described to achieve a 1X chemical/0.5% final DMSO concentration with subsequent addition of 10µL of ^{125}I dilution (final [^{125}I]: 329pM; 2.88pg/well) for a final reaction volume of 70µL/well. With this dilution protocol, a 20 mM stock chemical would have a final test concentration of 100 µM. Cells were incubated at room temperature for 2 hours and then washed twice with 200µL ice-cold uptake buffer. All uptake buffer was aspirated from wells, plates were sealed, and read on a MicroBeta^2 plate reader (Perkin Elmer, Waltham, MA) using a detection protocol to measure CPM corresponding to intracellular ^{125}I concentration. Assays for single and multi-concentration screening of samples were replicated in three independent runs containing different passages of the cells (i.e., 3 independent biological replicates).

Cell Viability Assay

Cell viability assays were conducted in parallel with the RAIU assays to identify samples where a decrease in RAIU might be due to cytotoxicity. hNIS-HEK293T-EPA cells were seeded and grown in 96-well solid white assay plates (Corning, Corning, NY) and exposed to chemical samples as described for RAIU assay. CellTiter-Glo (Promega, Fitchburg, WI) reagent (70µL) was then added to each well and plates were shaken for 5 minutes at 700rpm. Plates were incubated at room temperature for 10 minutes and then read on a FLUOstar Omega plate reader (BMG Labtech, Cary, NC) using an endpoint luminescence protocol (top read) to measure relative light units (RLU) indicative of ATP concentration. Assays for multi-concentration screening of samples were

replicated in three independent runs containing different passages of the cells (i.e., 3 independent biological replicates).

Chemical Screening

Chemicals were tested in a tiered approach to maximize resources and testing efficiency. Initial radioactive iodide uptake (RAIU) assays were performed as a single-concentration screen to identify active samples for subsequent testing in a concentration-response format. Each of the 310 blinded samples was tested at the maximum concentration (100μM, with some exceptions owing to solubility limits, see Table 2) in three independent RAIU assays using distinct passages of hNIS-HEK293T-EPA cells (i.e., bioreplicates). The median response for each sample from the three bioreplicates of the RAIU assays was used to determine whether the sample was active. Chemical samples were identified as active if the median RAIU inhibition was larger than a pre-determined activity threshold (20% in this study, refer to the data analysis section). Putative NIS inhibitors (i.e. active samples) were retested at six concentrations (obtained from 10-fold serial dilutions beginning with the maximum concentration, Table 2) in parallel RAIU and cell viability assays. The assay plate maps for single concentration screening and concentration-response assays are provided in Supplemental Figure 1.

Identification of Iodide Interference using Sandell-Kolthoff Reaction

Sandell-Kolthoff (SK) reaction is a colorimetric method to quantify iodide concentration through measurement of the iodide-catalyzed conversion of Ce^{4+} (yellow) to Ce^{3+} (colorless) [ADDIN EN.CITE ADDIN EN.CITE.DATA]. SK reaction assay was used to detect the presence of

iodide contamination or structural iodide in chemical samples that could possibly interfere with the RAIU assay and cause a false positive response. All 310 samples were tested by SK reaction following a previously developed protocol [ADDIN EN.CITE <EndNote><Cite><Author>Hallinger</Author><Year>2017</Year><RecNum>64</RecNum><DisplayText>(Hallinger<style face="italic"> et al.</style>, 2017)</DisplayText><record><rec-number>64</rec-number><foreign-keys><key app="EN" db-id="tsarvxesktrfvwe9d9rxsxthda0dev5r55ef" timestamp="1490798592">64</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Hallinger, Daniel R.</author><author>Murr, Ashley S.</author><author>Buckalew, Angela R.</author><author>Simmons, Steven O.</author><author>Stoker, Tammy E.</author><author>Laws, Susan C.</author></authors></contributors><titles><title>Development of a screening approach to detect thyroid disrupting chemicals that inhibit the human sodium iodide symporter (NIS)</title><secondary-title>Toxicology in Vitro</secondary-title></titles><periodical><full-title>Toxicology in Vitro</full-title></periodical><pages>66-78</pages><volume>40</volume><keywords><keyword>Thyroid</keyword><keyword>Endocrine disruptors</keyword><keyword>Sodium iodide symporter</keyword><keyword>Chemical screening</keyword></keywords><dates><year>2017</year><pub-dates><date>4//</date></pub-dates></dates><isbn>0887-2333</isbn><urls><related-urls><url>http://www.sciencedirect.com/science/article/pii/S0887233316302569</url><url>http://ac.els-cdn.com/S0887233316302569/1-s2.0-S0887233316302569-main.pdf?_tid=286edb04-

d8fa-11e6-b2db-

00000aacb360&acdnat=1484248141_9bcc422b76262b7c7843748a566dbb7c</url></related-urls></urls><electronic-resource-num>http://dx.doi.org/10.1016/j.tiv.2016.12.006</electronic-resource-num></record></Cite></EndNote>]. Briefly, 0.35µL of 100µM chemical samples were transferred to assay plate wells containing 69.7µL uptake buffer. Then standards (NaI, 100, 200, 300, 400, 500 nM) were added to specified duplicate wells at 70µL each. To initiate the reaction, 70µL of 24mM sodium arsenite solution and 70µL of 9.9 mM ammonium cerium sulfate solution was added to all wells. The reaction was incubated for 20 minutes at room temperature and subsequently measured for absorbance at 420nm on a SpectraMax Plus Microplate Reader (Molecular Devices, Sunnyvale, CA). Raw A_{420} readings were log10-transformed and NaI standards readings were fitted with linear regression to interpolate iodide concentration for each chemical. All testing was performed in triplicates.

Data analysis

Data analysis was performed in R (ver 3.3.0; R Foundation for Statistical Computing) and documented in R markdown (Supplemental File 1).

Single-concentration screening analysis

RAIU assay raw readings were measured as counts per minute (CPM) and normalized per 96-well plate as the percent activity of the median DMSO control CPM value (n = 12). The median of normalized percent activity from the 3 bioreplicates for each chemical was used to determine whether the chemical would be further evaluated in multi-concentration testing. The activity

threshold was set based on 3 times the baseline median absolute deviation (3bMAD) calculated using DMSO wells from all 15 assay plates in single-concentration screening. As 3bMAD was calculated to be 20.5%, the value for the activity inhibition threshold was rounded to 20% as a more conservative approach for moving chemicals forward to the multi-concentration RAIU and cell viability assays.

Multi-concentration screening analysis

Multi-concentration RAIU assay readings were expressed as CPM and cell viability assay readings were expressed as relative light unit (RLU). Both RAIU and cell viability assay raw readings were normalized using the same method employed in the single-concentration assay.

Dose-response curves were fitted using the Hill model provided in U.S. EPA's ToxCast Pipeline (tcpl v1.2.2) R package [ADDIN EN.CITE <EndNote><Cite><Author>Filer</Author><Year>2017</Year><RecNum>16</RecNum><DisplayText>(Filer<style face="italic"> et al.</style>, 2017)</DisplayText><record><rec-number>16</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1493134067">16</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Filer, Dayne L.</author><author>Kothiya, Parth</author><author>Setzer, R. Woodrow</author><author>Judson, Richard S.</author><author>Martin, Matthew T.</author></authors></contributors><titles><title>tcpl: the ToxCast pipeline for high-throughput screening data</title><secondary-title>Bioinformatics</secondary-title></titles><periodical><full-title>Bioinformatics</full-title></periodical><pages>618-

620</pages><volume>33</volume><number>4</number><dates><year>2017</year></dates>
<isbn>1367-4803</isbn><urls><related-
urls><url>http://dx.doi.org/10.1093/bioinformatics/btw680</url></related-
urls></urls><electronic-resource-num>10.1093/bioinformatics/btw680</electronic-resource-
num></record></Cite></EndNote>]. The Hill model contains three parameters with bottom asymptote constrained to 0 and is given by the formula:

$$f(x,(tp,ga,gw)) = \frac{tp}{1+10^{(ga-x)gw}}$$

Where x is the log concentration, tp is the top asymptote for the given chemical, ga is the AC_{50} (the log concentration where the modeled activity equals 50% of the top asymptote), and gw is the Hill coefficient. The Hill model provided in the tcpl R package constrains the three parameters as following:

(1) $0 \leq tp \leq 1.2$ times the maximum response value

(2) (minimum log concentration minus 2) $\leq ga \leq$ (maximum log concentration plus 0.5)

(3) $0.3 \leq gw \leq 8$

Prior to curve fitting, the modeling function in the tcpl R package first checked for significant response by comparing the median of normalized chemical responses at each concentration to the 3bMAD value of each assay. The 3bMAD of the multi-concentration RAIU and cell viability assay (23.8% and 17.7% respectively) were calculated separately for each assay using the normalized

response values collected from the two lowest concentrations of all test chemical samples. Curve fitting was only performed when a significant response was present.

Prior to curve fitting, the normalized multi-concentration response data were inversed by using 100 minus the normalized value. This was done because the modeling function in the tcpl R package requires multi-concentration assay data to be conformed in the positive direction, whereas the RAIU and cell viability assay results were in the negative direction (inhibition from maximal response). Predicted response values (yhat) were calculated using the fitted Hill model parameters for each chemical. To visualize assay data and fitted dose-response curve together in the original negative direction, yhat values were subtracted by 100 and used to plot the dose-response curve. The normalized RAIU and cell viability responses, along with their fitted dose-response curve were plotted together in one graph for each chemical using the R package ggplot2 v2.2 [ADDIN EN.CITE

Calculation of Z', CV of DMSO, AC_{50}, $absEC_{50}$, Cytotox-point

[PAGE * MERGEFORMAT]

To monitor the performance of the assay, quality control measures including Z' scores, coefficients of variation (CV) of DMSO, and AC_{50} of positive controls ($NaClO_4$ for RAIU, DCNQ for cell viability) were calculated by each 96-well assay plate. CV of DMSO was calculated by the equation: $CV = SD_{DMSO}/\mu_{DMSO}$, where SD_{DMSO} and μ_{DMSO} are the standard deviation and mean of the raw response value for DMSO control wells, respectively. Z' scores [ADDIN EN.CITE <EndNote><Cite><Author>Zhang</Author><Year>1999</Year><RecNum>65</RecNum><DisplayText>(Zhang<style face="italic"> et al.</style>, 1999)</DisplayText><record><rec-number>65</rec-number><foreign-keys><key app="EN" db-id="tsarvxesktrfvwe9d9rxsxthda0dev5r55ef" timestamp="1490798592">65</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Zhang, Ji-Hu</author><author>Chung, Thomas D. Y.</author><author>Oldenburg, Kevin R.</author></authors></contributors><titles><title>A Simple Statistical Parameter for Use in Evaluation and Validation of High Throughput Screening Assays</title><secondary-title>Journal of Biomolecular Screening</secondary-title></titles><periodical><full-title>J Biomol Screen</full-title><abbr-1>Journal of biomolecular screening</abbr-1></periodical><pages>67-73</pages><volume>4</volume><number>2</number><dates><year>1999</year><pub-dates><date>1999/04/01</date></pub-dates></dates><publisher>SAGE Publications</publisher><isbn>1087-0571</isbn><urls><related-urls><url>http://journals.sagepub.com/doi/abs/10.1177/108705719900400206</url></related-urls></urls><electronic-resource-num>10.1177/108705719900400206</electronic-resource-num><access-date>2017/02/03</access-date></record></Cite></EndNote>] were calculated as:

$$Z' = 1 - \frac{3(\sigma_{pos} + \sigma_{DMSO})}{|\mu_{pos} - \mu_{DMSO}|}$$

Where σ_{pos} and μ_{pos} are the standard deviation and mean of normalized positive control ($NaClO_4$ for RAIU assay, DCNQ for cell viability assay) values at the highest 100 μM concentration. σ_{DMSO} and μ_{DMSO} are the standard deviation and mean of normalized DMSO control values. AC_{50} (the log concentration where the modeled activity equals 50% of the chemical's modeled maximal activity) was reported for all chemicals with fitted dose-response curves. For chemicals that inhibited iodide uptake by > 50%, absolute EC_{50} ($absEC_{50}$) were also reported. $absEC_{50}$ was determined as the log concentration where the modeled activity equals 50% of control activity. absEC80 was determined as the log concentration where the modeled activity equals 80% of control activity.

For chemicals that demonstrated significant cytotoxicity (exceeding 3bMAD of cell viability assay, 17.7%), the concentration where a significant reduction in cell viability for each chemical was determined and referred to as the cytotox-point. Cytotox-point is the equivalent of $absEC_{82.3}$, the log concentration where the modelled activity equals the significant cytotoxicity cutoff value (82.3% of control viability).

Chemical ranking score

To prioritize the chemicals for potential NIS inhibition activity, a new ranking system was developed based on two metrics that take into account the confounding impact of cytotoxicity on identifying RAIU inhibition activity: 1) toxicity-adjusted area (TAA) and 2) the difference of median responses of RAIU and cytotoxicity at maximum tested concentration (Median-Difference)

(Fig. 1). Ranking analysis was only performed if a chemical produced significant RAIU inhibition in multi-concentration screening. To obtain TAA (gray stripe area illustrated in Fig.1), RAIU inhibition area and cytotoxicity area were first calculated. RAIU inhibition area was defined by the RAIU 3bMAD (23.8%) significant threshold horizontal line (top border), maximum concentration vertical line (right border), and the RAIU dose-response curve. Cytotoxicity area was defined with the same top and right borders and the cell viability dose-response curve. TAA was then obtained by subtracting the cytotoxicity area from the RAIU inhibition area. Therefore, the numeric value of TAA is penalized when a chemical demonstrates strong cytotoxicity. Median-Difference was calculated using the median of cell viability responses minus the median of RAIU responses at the maximum tested concentration (usually 100 μM). Larger Median-Difference values represent larger separations between RAIU and cytotoxicity.

To rank test chemicals, the well-known NIS inhibitor $NaClO_4$ was chosen as the reference chemical to normalize the TAA and Median-Difference of each test chemical. Specifically, the TAA and Median-Difference values of $NaClO_4$ positive control included on each of the 54 multi-concentration testing plates were first calculated to obtain the median of $NaClO_4$ TAA and Median-Difference (150.03 and 95.67 respectively). The TAA and Median-Difference of test chemicals were normalized as the percentage of the median $NaClO_4$ TAA and Median-Difference separately and then summed to obtain a chemical ranking score. The ranking score of 200 represents the potency of the reference $NaClO_4$ (Fig. 1A). Fig. 1B, 1C and 1D show the dose-response of three test chemicals with lower level of ranking scores due to less RAIU inhibition and increased cytotoxicity level.

[PAGE * MERGEFORMAT]

Results

Single-concentration screening

To facilitate the screening process, the 310 blinded samples were first tested in the RAIU assay at their maximum permissible concentration (typically at 100 μM, Table 2) to select potentially active compounds for concentration-response evaluation. Assay performance of single-concentration screening was monitored for each assay plate (total number of plates = 15) through CV of DMSO vehicle control, Z' and AC_{50} for the positive control chemical $NaClO_4$ (Table 3). The CV of DMSO control wells for each plate ranged from 4.91% to 11.04%, with mean ± SD of 7.14% ± 1.56%. Z' scores ranged from 0.65 to 0.84, with mean ± SD of 0.77 ± 0.05. AC_{50} (logM) of $NaClO_4$ ranged from -6.56 to -6.06, with mean ± SD of -6.44 ± 0.11. In addition, the responses of control chemicals included on each assay plate are summarized for the entire screening campaign in Table 4. The DMSO (vehicle control), 2,4-D (negative control), $NaNO_3$ (EC_{80} positive control), NaSCN (EC_{20} positive control) achieved mean ± SD of 100.63% ± 7.11%, 92.41% ± 4.24%, 81.25% ± 7.56%, 20.64% ± 1.12%, respectively. Overall, these metrics indicate the RAIU assay in single-concentration screening performed well with sufficient dynamic range, reproducibility, and reliability.

Single-concentration RAIU screening results for all 310 samples were ordered by increasing inhibitory median responses and plotted as median and maximum/minimum responses for each sample (Fig.2). These samples demonstrated a wide range of iodide uptake inhibition activity in the assay with median responses ranging from 2.8% to 116.6% of maximum iodide uptake relative

to DMSO control. Of the 310 samples, 169 samples (54.5%) produced over the pre-determined 20% inhibition threshold and were selected for multi-concentration testing (Table 2).

Blinded internal replicate chemicals

The phase I_v2 chemical library consisted of 310 blinded samples that included 293 unique chemicals. Twelve of these chemicals were internally replicated (7 chemicals replicated twice and 5 chemicals replicated three times) to assess assay reproducibility. The robustness of the RAIU assay is shown in Fig. 3a, where all 12 replicated chemicals, excepting bisphenol A, produced highly reproducible results. Of the 12 replicated chemicals, 10 exceeded the 20% inhibition threshold and were subsequently tested in multi-concentration screening. The AC_{50} for each replicate of the 10 chemicals was calculated to assess the reproducibility of the RAIU assay in the multi-concentration setting (Fig. 3b, Supplemental Table 1). These 10 internal replicate samples had highly reproducible AC_{50} (logM) values with the maximum range of variation less than 0.25 (logM).

Multi-concentration testing

The 169 blinded samples with ≥20% inhibition in single-concentration RAIU screening were retested at 6 concentrations (0.001μM – 100μM) in parallel RAIU and cell viability assays. Both RAIU and cell viability assays performed reliably and their performance metrics calculated by each assay plate (total number of plates = 54) are summarized in Table 3. The CV of DMSO controls for RAIU and cell viability assays had mean ± SD of 8.61% ± 1.01%, 5.42% ± 1.47%, respectively. The Z' for the RAIU assay had a range of 0.64 - 0.78 and mean ± SD of 0.72 ± 0.03.

The AC_{50} (logM) of positive controls ($NaClO_4$ for the RAIU assay, DCNQ for the cell viability assay) also demonstrated high reproducibility across assay plates, with mean ± SD of -6.38 ± 0.13, -4.83 ± 0.12 for RAIU and cell viability assays, respectively. The dose-response curves of $NaClO_4$ and DCNQ positive controls in multi-concentration screening are provided in Supplemental Figure 3. Additionally, the responses of all control chemicals are summarized across all assay plates in Table 4. All controls of the RAIU and cell viability assays showed great consistency with small variances in multi-concentration testing. The DMSO (vehicle control), 2,4-D (RAIU negative control), $NaNO_3$ (RAIU EC_{80} positive control), and NaSCN (RAIU EC_{20} positive control) achieved mean ± SD of 99.5% ± 8.28%, 90.86% ± 4.49%, 83.08% ± 7.17%, and 24.69% ± 2.71% respectively in RAIU assay. In the cell viability assay, DMSO, 2,4-D, $NaNO_3$, and NaSCN were inactive, with responses (mean±SD) of 100.92% ± 5.41%, 99.34% ± 3.21%, 98.95% ± 5.43%, and 104.3% ± 3.98%, respectively.

The significant activity threshold (3bMAD, calculated across all 54 assay plates in multi-concentration screening) for cell viability and RAIU assays were 17.7% and 23.8%, respectively. Among the 169 tested samples, 137 showed significant RAIU inhibition activity (>23.8% inhibition) and 127 exhibited significant cytotoxicity (>17.7% inhibition). Within the 137 samples with significant RAIU inhibition activity, 111 displayed a cytotoxic response while no change in cell viability was observed in 26 samples. There were 16 chemicals that caused significant cytotoxicity with no significant RAIU inhibition.

In reporting the RAIU and cell viability responses of each test chemical, several activity metrics, including AC_{50}, $absEC_{50}$, and cytotox-point (Table 2) were used together to aid in the interpretation of the assay results. AC_{50} and $absEC_{50}$ indicate the chemical potency from two different perspectives, as they differ in the inhibition activity level each represents. $absEC_{50}$ is the concentration that causes 50% inhibition, while AC_{50} is the concentration that triggers half-maximal inhibition, which is <50% inhibition for chemicals that do not fully inhibit NIS activity at the maximal concentration tested. AC_{50} is a useful metric to rank potencies even if the test chemical has low efficacy, provided that an activity curve can be fit. However, AC_{50} is not suitable to compare chemicals with different maximum inhibition activities, as their AC_{50} values represent the effective concentrations at different absolute activity levels. Moreover, the AC_{50} value of any given chemical may shift if it can produce stronger inhibition at higher test concentrations. To avoid these two issues, $absEC_{50}$ was calculated and reported. A reported $absEC_{50}$ value also indicates that the chemical exhibited ≥50% inhibition in the RAIU assay. For quick reference of the occurrence of cytotoxicity, the cytotox-point, which represents the concentration where significant cytotoxicity was observed, was reported along with the AC_{50} and $absEC_{50}$ values. Dose-response curves for each chemical are available in Supplemental Figure 2. AC50 and absEC50 values for cell viability assay are provided in Supplemental Table 2.

When comparing results from the highest concentration in multi-concentration screening and single-concentration screening, 87% of the chemicals (147 of 169) tested in multi-concentration format produced over 20% inhibition in RAIU assay, the significance threshold chosen for the single-concentration screening. Twenty-two chemicals failed to meet the 20% inhibition threshold

during multi-concentration testing. The range of their median RAIU inhibition in the initial single-concentration screen was between 20.9% to 51.8%, and 14 of the 22 chemicals had a median inhibition below 30%, indicating that these chemicals were weak actives in the initial single-concentration screen.

Chemical potency ranking

To prioritize chemicals for further analysis, the 169 samples tested in multi-concentration were further analyzed by a newly developed ranking system that estimates the RAIU inhibitory potency while mitigating the negative impact of cytotoxicity on identifying RAIU activity (Fig. 1). Of the 169 chemical samples tested in multi-concentration, 32 did not produce significant RAIU inhibition and hence were excluded in the ranking analysis. The ranking scores of the 137 chemical samples are listed and illustrated in Table 2 and Fig. 4. The TAA and Median-Difference values for these chemicals are provided in Supplemental Table 2.

In this study, the reference chemical $NaClO_4$ exhibited the most potent RAIU inhibition with a ranking score of 200 (both TAA and Median-Difference valued at 100). In comparison, the ranking score of the 137 test chemical samples ranged from 150.41 to -29.52, with 4 having ranking scores >100, 17 having ranking scores between 50 and 100, and 116 having ranking scores <50. An overview of the cytotoxicity of the ranked chemicals at the maximum concentration tested is shown in Fig. 4. Of the 137 chemical samples that produced significant RAIU inhibition, 27 exhibited no cytotoxicity, 67 exhibited significant but <50% cytotoxicity, and 43 exhibited >50% cytotoxicity at the maximum concentration.

The dose-response curves along with the ranking score, AC_{50} and $absEC_{50}$ for the first 15 ranked samples (14 chemicals) are shown in Fig. 5a. These 15 samples have ranking score ranged from 150.41 to 64.10, AC50 ranged from -4.33 to -8.64, absEC50 ranged from -4.37 to -7.49. Fig. 5b shows three examples of the 32 chemicals that failed to produce significant RAIU inhibition, with either no significant or nominal cytotoxicity.

Identification of Iodide interference

The 310 samples were also tested with SK reactions to determine the presence of any contaminant iodide that may lead to potential false positive RAIU inhibition. Only two chemicals (iodosulfuron-methyl-sodium and 3-iodo-2-propynyl-N-butylcarbamate) produced positive SK reactions, suggesting that overall iodide contamination was not introducing false positive results in the RAIU assay. Iodosulfuron-methyl-sodium produced a positive SK reaction with interpolated content of 12.69 ± 1.12 pmol/well of equivalent I^-. However, this chemical had <20% RAIU inhibition in the single-concentration screening and therefore was not tested in the multi-concentration assay. 3-iodo-2-propynyl-N-butylcarbamate produced A_{420} readings beyond the upper range of the standard curve (> 35pmol/well). However, since 3-iodo-2-propynyl-N-butylcarbamate structurally contains iodide, it is unclear whether the strong S-K reaction was triggered by the chemical itself or the iodide contamination in the sample. This uncertainty about iodide contamination confounds any intrepetation of 3-iodo-2-propynyl-N-butylcarbamate results as an efficaious NIS inhibitor in the RAIU assay.

Discussion

This study represents the first large-scale screening effort to identify potential NIS inhibitors in an environmental chemical library using our previously developed HTS approach [ADDIN EN.CITE <EndNote><Cite><Author>Hallinger</Author><Year>2017</Year><RecNum>64</RecNum><DisplayText>(Hallinger<style face="italic"> et al.</style>, 2017)</DisplayText><record><rec-number>64</rec-number><foreign-keys><key app="EN" db-id="tsarvxesktrfvwe9d9rxsxthda0dev5r55ef" timestamp="1490798592">64</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Hallinger, Daniel R.</author><author>Murr, Ashley S.</author><author>Buckalew, Angela R.</author><author>Simmons, Steven O.</author><author>Stoker, Tammy E.</author><author>Laws, Susan C.</author></authors></contributors><titles><title>Development of a screening approach to detect thyroid disrupting chemicals that inhibit the human sodium iodide symporter (NIS)</title><secondary-title>Toxicology in Vitro</secondary-title></titles><periodical><full-title>Toxicology in Vitro</full-title></periodical><pages>66-78</pages><volume>40</volume><keywords><keyword>Thyroid</keyword><keyword>Endocrine disruptors</keyword><keyword>Sodium iodide symporter</keyword><keyword>Chemical screening</keyword></keywords><dates><year>2017</year><pub-dates><date>4//</date></pub-dates></dates><isbn>0887-2333</isbn><urls><related-urls><url>http://www.sciencedirect.com/science/article/pii/S0887233316302569</url><url>http

://ac.els-cdn.com/S0887233316302569/1-s2.0-S0887233316302569-main.pdf?_tid=286edb04-d8fa-11e6-b2db-00000aacb360&acdnat=1484248141_9bcc422b76262b7c7843748a566dbb7c</url></related-urls></urls><electronic-resource-num>http://dx.doi.org/10.1016/j.tiv.2016.12.006</electronic-resource-num></record></Cite></EndNote>]. The results demonstrate that this assay performed with high reproducibility and reliability as measured by typical performance metrics for HTS assays. The assay demonstrated a high Z' score and low variability in DMSO vehicle controls in both the single- and multi-concentration RAIU screenings. The internal chemical replicates, included for quality control purposes, also demonstrated consistent responses that further support strong assay reproducibility.

Prioritizing chemical RAIU inhibition potency based on a cell-based assay can be confounded if the test compound exhibits strong cytotoxicity. Therefore, a great effort was made to conduct a parallel cell viability assay using the same batch of cell culture, the same treatment and experimental conditions with the RAIU assay to provide the best possible estimation of cytotoxicity. To maximize the usage of the rigorous cytotoxicity data, a novel potency ranking system was developed to prioritize potential NIS inhibitors. Based on both RAIU and cytotoxicity dose-responses, this system adapts cytotoxicity in calculating the two underlying metrics, TAA and Median-Difference. The ranking score was also normalized in reference to the well-known NIS inhibitor sodium perchlorate, making it compatible for comparisons with chemicals in future screenings. Overall, this ranking system enhances the quality of chemical prioritization when compared to other systems that rely on single point metrics. With this ranking system, the top

ranked 15 samples (Fig. 5a) represent a diverse group of 14 environmental chemicals with different known toxicological properties and are further discussed below.

Several of these highly ranked chemicals are pesticides that showed potential effects on cellular energy. For example, etoxazole is an organofluorine acaricide-insecticide and was the highest ranked among all the tested chemicals, with a typical sigmoidal RAIU inhibition response and minimal cytotoxicity (25.2% median inhibition) at the highest test concentration. The U.S. EPA ToxRef database [ADDIN EN.CITE <EndNote><Cite><Author>Martin</Author><Year>2009</Year><RecNum>59</RecNum><DisplayText>(Martin<style face="italic"> et al.</style>, 2009)</DisplayText><record><rec-number>59</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1499258815">59</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Martin, MT</author><author>Judson, RS</author><author>Reif, DM</author><author>Kavlock, RJ</author><author>Dix, DJ</author></authors></contributors><titles><title>Profiling chemicals based on chronic toxicity results from the US EPA ToxRef Database</title><secondary-title>Environmental Health Perspectives</secondary-title></titles><periodical><full-title>Environmental Health Perspectives</full-title></periodical><pages>392-399</pages><volume>117</volume><number>3</number><dates><year>2009</year></dates><isbn>0091-6765</isbn><urls></urls></record></Cite></EndNote>], a collection of curated *in vivo* regulatory toxicity information previously submitted to the agency, reveals that etoxazole can lead to increase of thyroid gland weight in both subchronic and chronic rat oral toxicity studies.

Our finding is the first to show that etoxazole disrupts iodide uptake by NIS. However, whether etoxazole can directly interact with the NIS protein requires further investigation, as a study on the freshwater fish *Oreochromis niloticus* found that etoxazole exposure at high concentration can lead to increase of Na^+/K^+ ATPase activities in gill and muscle and a decrease of this activity in kidney [ADDIN EN.CITE <EndNote><Cite><Author>Üner</Author><Year>2005</Year><RecNum>42</RecNum><DisplayText>(Üner<style face="italic"> et al.</style>, 2005)</DisplayText><record><rec-number>42</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1496349898">42</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Üner, Nevin</author><author>Oruç, Elif</author><author>Sevgiler, Yusuf</author></authors></contributors><titles><title>Oxidative stress-related and ATPase effects of etoxazole in different tissues of Oreochromis niloticus</title><secondary-title>Environmental Toxicology and Pharmacology</secondary-title></titles><periodical><full-title>Environmental Toxicology and Pharmacology</full-title></periodical><pages>99-106</pages><volume>20</volume><number>1</number><keywords><keyword>Etoxazole</keyword><keyword>Antioxidant enzyme</keyword><keyword>Oxidative stress</keyword><keyword>Lipid peroxidation</keyword><keyword>ATPase</keyword><keyword>Fish tissues</keyword></keywords><dates><year>2005</year><pub-dates><date>7//</date></pub-dates></dates><isbn>1382-6689</isbn><urls><related-urls><url>http://www.sciencedirect.com/science/article/pii/S1382668904002418</url><url>http

://ac.els-cdn.com/S1382668904002418/1-s2.0-S1382668904002418-main.pdf?_tid=2d359ba4-39a4-11e7-8f97-00000aab0f26&acdnat=1494876475_48b693815708540978a9cf4a54820f14</url></related-urls></urls><electronic-resource-num>https://doi.org/10.1016/j.etap.2004.11.006</electronic-resource-num></record></Cite></EndNote>]. Since Na^+/K^+ ATPase maintains the critical cross-membrane sodium gradient necessary for NIS functionality, disruption of Na^+/K^+ ATPase activity can indirectly affect NIS activity. Another high-ranking chemical, niclosamide, may also have interfered with NIS function indirectly, as it is a pharmaceutical that uncouples oxidative phosphorylation in mitochondria [ADDIN EN.CITE <EndNote><Cite><Author>Pearson</Author><Year>1985</Year><RecNum>43</RecNum><DisplayText>(Pearson and Hewlett, 1985)</DisplayText><record><rec-number>43</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1496349898">43</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Pearson, R. D.</author><author>Hewlett, E. L.</author></authors></contributors><titles><title>NIclosamide therapy for tapeworm infections</title><secondary-title>Annals of Internal Medicine</secondary-title></titles><periodical><full-title>Annals of Internal Medicine</full-title></periodical><pages>550-551</pages><volume>102</volume><number>4</number><dates><year>1985</year></dates><isbn>0003-4819</isbn><urls><related-urls><url>http://dx.doi.org/10.7326/0003-4819-102-4-550</url></related-urls></urls><electronic-resource-num>10.7326/0003-4819-102-4-550</electronic-resource-num></record></Cite></EndNote>], thereby disrupt ATP production

and hence Na^+/K^+ ATPase activity. To date, there is no report of niclosamide regarding thyroid toxicity, except its anti-proliferative effect in human thyroid cancer cells [ADDIN EN.CITE <EndNote><Cite><Author>Zhang</Author><Year>2012</Year><RecNum>44</RecNum><DisplayText>(Zhang<style face="italic"> et al.</style>, 2012)</DisplayText><record><rec-number>44</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1496349899">44</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Zhang, Lisa</author><author>He, Mei</author><author>Zhang, Yaqin</author><author>Nilubol, Naris</author><author>Shen, Min</author><author>Kebebew, Electron</author></authors></contributors><titles><title>Quantitative High-Throughput Drug Screening Identifies Novel Classes of Drugs with Anticancer Activity in Thyroid Cancer Cells: Opportunities for Repurposing</title><secondary-title>The Journal of Clinical Endocrinology & Metabolism</secondary-title></titles><periodical><full-title>The Journal of Clinical Endocrinology & Metabolism</full-title></periodical><pages>E319-E328</pages><volume>97</volume><number>3</number><dates><year>2012</year></dates><isbn>0021-972X</isbn><urls><related-urls><url>http://dx.doi.org/10.1210/jc.2011-2671</url></related-urls></urls><electronic-resource-num>10.1210/jc.2011-2671</electronic-resource-num></record></Cite></EndNote>].

Several other insecticides in this study have been shown to disrupt energy metabolism and demonstrated similar atypical RAIU dose-response curves that may implicate an alternative mechanism of NIS inhibition. These chemicals include rotenone and pyridaben (Fig. 5a), which

are both mitochondrial complex I inhibitors that disrupt electron transport leading to reduced ATP production [ADDIN EN.CITE <EndNote><Cite><Author>Hollingworth</Author><Year>1994</Year><RecNum>102</RecNum><DisplayText>(Hollingworth<style face="italic"> et al.</style>, 1994)</DisplayText><record><rec-number>102</rec-number><foreign-keys><key app="EN" db-id="tsarvxesktrfvwe9d9rxsxthda0dev5r55ef" timestamp="1496174640">102</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Hollingworth, R. <EndNote><Cite><Author>Martin</Author><Year>2009</Year><RecNum>59</RecNum><DisplayText>(Martin<style face="italic"> et al.</style>, 2009)</DisplayText><record><rec-number>59</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1499258815">59</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Martin, MT</author><author>Judson, RS</author><author>Reif, DM</author><author>Kavlock, RJ</author><author>Dix, DJ</author></authors></contributors><titles><title>Profiling chemicals based on chronic toxicity results from the US EPA ToxRef Database</title><secondary-title>Environmental Health Perspectives</secondary-title></titles><periodical><full-title>Environmental Health Perspectives</full-title></periodical><pages>392-399</pages><volume>117</volume><number>3</number><dates><year>2009</year></dates><isbn>0091-6765</isbn><urls></urls></record></Cite></EndNote>]. Several lower ranked chemicals (Supplemental Fig. 2) including fenpyroximate, tebufenpyrad (mitochondrial NADH-CoQ reductase inhibitor), and pyraclostrobin (quinone inhibitor) may also disrupt energy levels [ADDIN EN.CITE ADDIN EN.CITE.DATA]. These chemicals have similar atypical dose-responses in the RAIU assay with a very flat slope and they all produced significant effects on cell viability. Since the Cell-Titer Glo viability assay quantifies ATP as an indicator of viable cells, this effect on cell viability could be the result of either energy metabolism disruption or cell death. A secondary cell viability assay using an alternative indicator of viability can confirm the cytotoxicity observed.

Several chemicals in the top 14 chemicals, including PFOS, triphenyltin hydroxide, and fipronil have been shown to disrupt thyroid function in previous studies and had significant effects on iodide uptake by NIS in the current study. Among these three chemicals, PFOS has been the most studied due to its widespread presence and persistence in the environment. PFOS was reported to decrease serum T4 levels in mammalian models such as the rat, mouse, and monkey [ADDIN EN.CITE ADDIN EN.CITE.DATA]. Aquatic exposure to PFOS has also been shown to increase T3 level, upregulate NIS expression, and alter expression of other HPT genes in zebrafish larvae [ADDIN EN.CITE <EndNote><Cite><Author>Shi</Author><Year>2009</Year><RecNum>53</RecNum><DisplayText>(Shi<style face="italic"> et al.</style>, 2009)</DisplayText><record><rec-number>53</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1496349899">53</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Shi, Xiongjie</author><author>Liu, Chunsheng</author><author>Wu, Guoqiao</author><author>Zhou, Bingsheng</author></authors></contributors><titles><title>Waterborne exposure to PFOS causes disruption of the hypothalamus–pituitary–thyroid axis in zebrafish larvae</title><secondary-title>Chemosphere</secondary-title></titles><periodical><full-title>Chemosphere</full-title></periodical><pages>1010-1018</pages><volume>77</volume><number>7</number><keywords><keyword>PFOS</keyword><keyword>Hypothalamic–pituitary–thyroid axis</keyword><keyword>Thyroid hormone</keyword><keyword>Zebrafish</keyword></keywords><dates><year>2009</year><

In this study, the two PFOS samples (internally replicated in ToxCast library) both produced significant RAIU inhibition with similar dose-responses (Fig. 6a). The absEC$_{50}$ values for the two PFOS samples were also very close with values of -4.78 and -4.74 (logM), respectively. Triphenyltin hydroxide is a fungicide that has been shown to impair reproduction in rats and cause reduced pituitary, thyroid weight, and increased incidence of pituitary tumors [ADDIN EN.CITE <EndNote><Cite><Author>Golub</Author><Year>2004</Year><RecNum>55</RecNum><DisplayText>(Golub and Doherty, 2004)</DisplayText><record><rec-number>55</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1496349899">55</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Golub, Mari S</author><author>Doherty, John D</author></authors></contributors><titles><title>Triphenyltin as a potential human endocrine disruptor</title><secondary-title>Journal of Toxicology and Environmental Health, Part B</secondary-title></titles><periodical><full-title>Journal of Toxicology and Environmental Health, Part B</full-title></periodical><pages>281-295</pages><volume>7</volume><number>4</number><dates><year>2004</year></dates><isbn>1093-7404</isbn><urls></urls></record></Cite></EndNote>]. A study with Japanese quail also reported decreased serum T4 level and impaired reproduction following triphenyltin

hydroxide dietary exposure [ADDIN EN.CITE <EndNote><Cite><Author>Grote</Author><Year>2006</Year><RecNum>56</RecNum><DisplayText>(Grote<style face="italic"> et al.</style>, 2006)</DisplayText><record><rec-number>56</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1496349899">56</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Grote, K.</author><author>Niemann, L.</author><author>Gericke, C.</author><author>Selzsam, B.</author><author>Chahoud, I.</author></authors></contributors><titles><title>Effects of fentin hydroxide on reproduction of the Japanese quail (Coturnix coturnix japonica)</title><secondary-title>Environmental Research</secondary-title></titles><periodical><full-title>Environmental Research</full-title></periodical><pages>81-88</pages><volume>101</volume><number>1</number><keywords><keyword>Fentin hydroxide</keyword><keyword>Organotin compounds</keyword><keyword>Japanese quail</keyword><keyword>Reproduction</keyword><keyword>Endorine disruption</keyword></keywords><dates><year>2006</year><pub-dates><date>5//</date></pub-dates></dates><isbn>0013-9351</isbn><urls><related-urls><url>http://www.sciencedirect.com/science/article/pii/S0013935105001015</url></related-urls></urls><electronic-resource-num>https://doi.org/10.1016/j.envres.2005.07.004</electronic-resource-num></record></Cite></EndNote>]. In our study, triphenyltin hydroxide demonstrated a typical RAIU inhibition dose-response (absEC50 = -5.39 logM) with moderate cytotoxicity only at 100 μM. Fipronil is a broadly used insecticide that has been associated with elevated rates of T4

elimination in the rat and increased hepatic enzyme activity was suggested to be the cause [ADDIN EN.CITE <EndNote><Cite><Author>Leghait</Author><Year>2009</Year><RecNum>57</RecNum><DisplayText>(Leghait<style face="italic"> et al.</style>, 2009)</DisplayText><record><rec-number>57</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1496349900">57</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Leghait, Julien</author><author>Gayrard, Véronique</author><author>Picard-Hagen, Nicole</author><author>Camp, Marion</author><author>Perdu, Elisabeth</author><author>Toutain, Pierre-Louis</author><author>Viguié, Catherine</author></authors></contributors><titles><title>Fipronil-induced disruption of thyroid function in rats is mediated by increased total and free thyroxine clearances concomitantly to increased activity of hepatic enzymes</title><secondary-title>Toxicology</secondary-title></titles><periodical><full-title>Toxicology</full-title></periodical><pages>38-44</pages><volume>255</volume><number>1–2</number><keywords><keyword>Thyroid disruptor</keyword><keyword>Rat</keyword><keyword>Clearance</keyword><keyword>UDPGT</keyword><keyword>Fipronil</keyword><keyword>5-Amino-1-[2,6-dichloro-4-(trifluoromethyl)phenyl]-4-(trifluoromethylsulfinyl)-1H-pyrazole-3-carbonitrile</keyword></keywords><dates><year>2009</year><pub-dates><date>1/8/</date></pub-dates></dates><isbn>0300-483X</isbn><urls><related-urls><url>http://www.sciencedirect.com/science/article/pii/S0300483X08004654</url></related-urls></urls><electronic-resource-num>https://doi.org/10.1016/j.tox.2008.09.026</electronic-

resource-num></record></Cite></EndNote>]. The same group later conducted a fipronil study in sheep and found that the thyroid disruption activity previously observed in the rat could not be replicated in rams, and only a moderate level of increased T4 clearance was observed in ewes [ADDIN EN.CITE <EndNote><Cite><Author>Leghait</Author><Year>2010</Year><RecNum>58</RecNum><DisplayText>(Leghait<style face="italic"> et al.</style>, 2010)</DisplayText><record><rec-number>58</rec-number><foreign-keys><key app="EN" db-id="09vdaavf8zzsfkefza7x90s6tasptssaefxe" timestamp="1496349900">58</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Leghait, Julien</author><author>Gayrard, Véronique</author><author>Toutain, Pierre-Louis</author><author>Picard-Hagen, Nicole</author><author>Viguié, Catherine</author></authors></contributors><titles><title>Is the mechanisms of fipronil-induced thyroid disruption specific of the rat: Re-evaluation of fipronil thyroid toxicity in sheep?</title><secondary-title>Toxicology Letters</secondary-title></titles><periodical><full-title>Toxicology Letters</full-title></periodical><pages>51-57</pages><volume>194</volume><number>3</number><keywords><keyword>Fipronil</keyword><keyword>Thyroid toxicicity</keyword><keyword>Endocrine disruptor</keyword><keyword>Toxicokinetic</keyword><keyword>Sheep</keyword></keywords><dates><year>2010</year><pub-dates><date>5/4/</date></pub-dates></dates><isbn>0378-4274</isbn><urls><related-urls><url>http://www.sciencedirect.com/science/article/pii/S0378427410000329</url></related-urls></urls><electronic-resource-num>https://doi.org/10.1016/j.toxlet.2010.01.018</electronic-

resource-num></record></Cite></EndNote>]. In our study, fipronil demonstrated significant RAIU inhibition between 10 μM and 100 μM and significant cytotoxicity at 100 μM.

Apart from the chemicals discussed above, five of the top 14 chemicals were only associated with thyroid disruption activity in the U.S.EPA ToxRef database but no other published literature. The records in ToxRef database indicate that 3-iodo-2-propynyl-N-butylcarbamate, cyprodinil, and methoxyfenozide were associated with pathological changes in thyroid gland in subchronic rat toxicity studies. Cyprodinil also caused increased thyroid gland weight. ToxRef database also has records for captan and oxyfluorfen reporting increased thyroid gland weight in chronic rat toxicity studies. However, record usability in ToxRef for captan and oxyfluorfen was labaled as "deficient evaluation" and "unacceptable", respectively. Hence, these results may be unreliable. Fluroxypyr-meptyl and 2-(thiocyanomethylthio)benzothiazole were not previously associated with thyroid disruption, though similarly structured benzothiozoles have previously been identified as thyroid peroxidase inhibitors [ADDIN EN.CITE <EndNote><Cite><Author>Hornung</Author><Year>2015</Year><RecNum>91</RecNum><DisplayText>(Hornung<style face="italic"> et al.</style>, 2015)</DisplayText><record><rec-number>91</rec-number><foreign-keys><key app="EN" db-id="tsarvxesktrfvwe9d9rxsxthda0dev5r55ef" timestamp="1494528450">91</key></foreign-keys><ref-type name="Journal Article">17</ref-type><contributors><authors><author>Hornung, Michael W.</author><author>Kosian, Patricia A.</author><author>Haselman, Jonathan T.</author><author>Korte, Joseph J.</author><author>Challis, Katie</author><author>Macherla,

Chitralekha</author><author>Nevalainen, Erica</author><author>Degitz, Sigmund J.</author></authors></contributors><titles><title>In Vitro, Ex Vivo, and In Vivo Determination of Thyroid Hormone Modulating Activity of Benzothiazoles</title><secondary-title>Toxicological Sciences</secondary-title></titles><periodical><full-title>Toxicological Sciences</full-title></periodical><pages>254-264</pages><volume>146</volume><number>2</number><dates><year>2015</year></dates><isbn>1096-6080</isbn><urls><related-urls><url>http://dx.doi.org/10.1093/toxsci/kfv090</url></related-urls></urls><electronic-resource-num>10.1093/toxsci/kfv090</electronic-resource-num></record></Cite></EndNote>].

The development and implementation of this approach to identify potential NIS inhibitors fills a critical gap in the capability to screen chemicals under the U.S.EPA's regulatory purview for thyroid disrupting activity. The findings reported here confirm that the cell-based screening approach can be effectively used to identify chemicals that directly compete with iodide for intracellular transport through the symporter, as well as those chemicals that alter NIS function by disruption of energy production required to maintain the sodium gradient. The use of a unique ranking system that incorporates the cytotoxicity response for each chemical provides a stronger foundation for further assessment of chemicals with commonalities in structural and toxicological properties and/or prioritization for further testing. Because of the likely alternative RAIU inhibition mechanisms among these chemicals, close examination of the dose-response is suggested rather than relying on a single metric such as the AC_{50} or $absEC_{50}$ to draw conclusions regarding NIS inhibition. In addition, as with most *in vitro* assays, chemical purity and solubility

limitations need to be considered, warranting additional secondary assay testing to further confirm initial findings for high priority chemicals. For example, a secondary assay such as the rat thyroid FRTL-5 cell line based RAIU assay would add confidence to any HTS findings. Lastly, as with any *in vitro* assay, considerations of absorption, distribution, metabolism, excretion (ADME) as well as potential compensatory feedback are needed before assuming that a chemical would result in altered thyroid synthesis with exposure *in vivo*. Additional studies using short-term *in vivo* assays, such as those that employ amphibian or weanling rat models, are warranted to further investigate the thyroid-disruptive potential of NIS inhibitors.

As public concern increases over the effects of environmental chemicals on thyroid hormone signaling, there is an urgent need to expand the current knowledge base and understanding of the risks of thyroid disruption by a broader range of compounds. Iodide uptake into the thyroid via NIS is the critical initial step of thyroid hormone biosynthesis and is a known target of thyroid disruption in humans and wildlife. The screening of 293 ToxCast chemicals in the current study represents the first large scale effort to investigate NIS as a molecular target of environmental chemicals that cover a broad spectrum of structural and toxicological properties. The ranking of potential NIS inhibitors can inform the prioritization of chemicals for secondary testing. This ranking method will prove useful for the imminent screening of the ToxCast phase II and e1K chemical libraries for putative NIS inhibitors. Moreover, these data provide an integral component of the U.S.EPA's EDSP initiative to expand the coverage of known molecular targets of chemical-induced thyroid disruption (Noyes *et al.* 2017), as well as to support the development of a series of OECD test guidelines to assess chemicals for thyroid disrupting activity.

Abbreviations

EDSP21 (Endocrine Disruptor Screening Program in the 21st century), OECD (The Organization for Economic Co-operation and Development), ToxCast (Toxicity Forecaster), CV (coefficient of variation), NIS (sodium iodide symporter), RAIU (radioactive iodide uptake), RLU (relative light unit), SD (standard deviation), T_3 (triiodothyronine), T_4 (thyroxine), TH (thyroid hormone), 3bMAD (three times the baseline median absolute deviation), DMSO (dimethylsulfoxide), 2,4-D (2,4-dichlorophenoxyacetic acid), DCNQ (2,3-dichloro-1,4-napthoquinone), HEK (human embryonic kidney), AOP (adverse outcome pathway), HTS (high-throughput screening), DMEM (Dulbecco's Modified Eagle Medium), CPM (counts per minute), TAA (toxicity-adjusted area), PFOS (perfluorooctanesulfonic acid), PFOA (perfluorooctanoic acid)

Figures

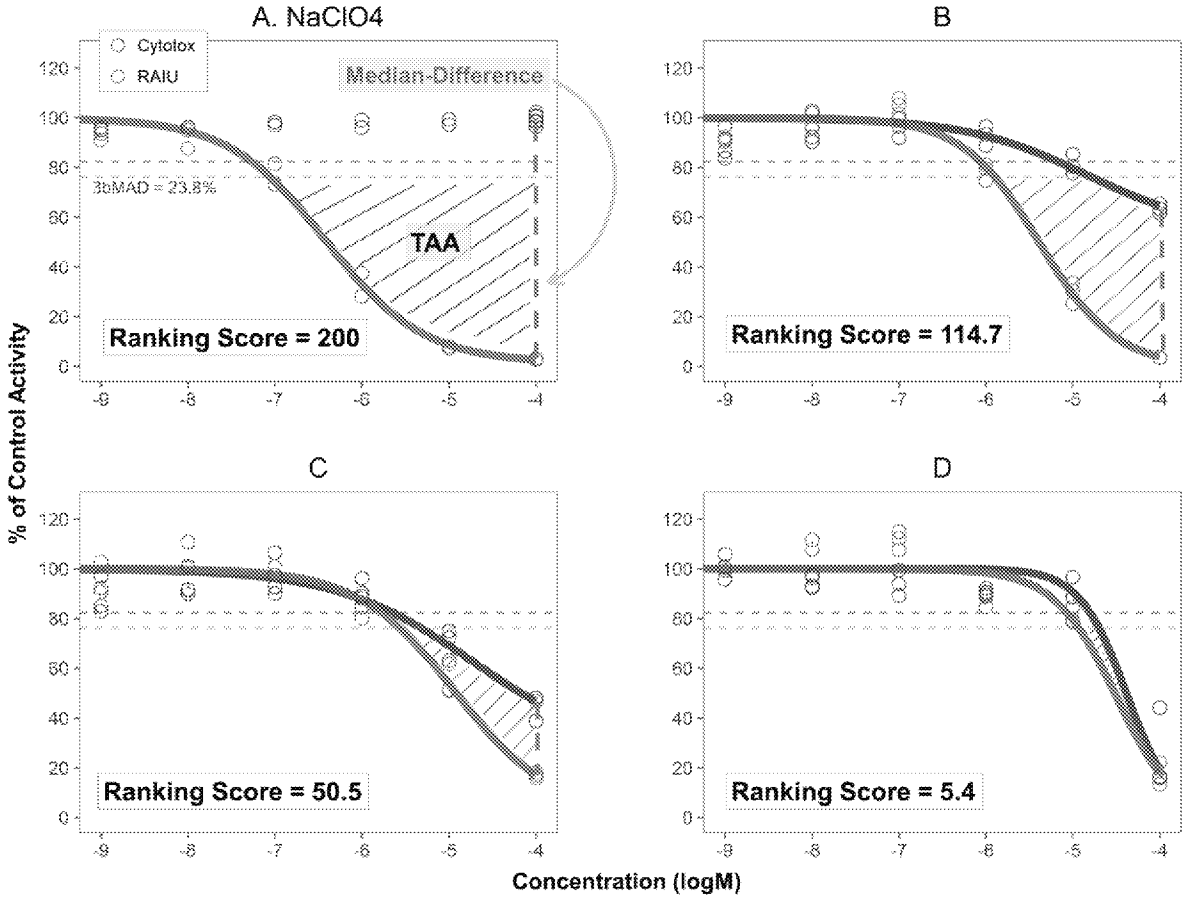

Fig. 1. Demonstration of ranking score, TAA and Median-Difference. Examples of chemical responses: A) sodium perchlorate, B) triphenyltin hydroxide, C) folpet, D) prodiamine. Cell viability and RAIU assay results are illustrated in red and blue respectively. The red and blue horizontal dotted lines represent the 3bMAD threshold for cell viability and RAIU assay respectively. Toxicity-adjusted area (TAA) is the gray striped area defined by 1) maximum concentration vertical line (right border), 2) the 3bMAD significant threshold horizontal line for RAIU assay (top border; blue dashed line), 3) the dose-response curve of RAIU and 4) if present,

the dose-response curve of cytotoxicity. The difference of median responses of RAIU and cytotoxicity at maximum tested concentration (Median-Difference) is indicated by the green vertical dotted line. Sodium perchlorate (A) was chosen as the reference NIS inhibitor to normalize test chemical TAA and Median-Difference as percentage values. Ranking score is obtained as the sum of normalized TAA and Median-Difference values. Therefore, sodium perchlorate has a ranking score of 200. B, C and D show three test chemicals with less RAIU inhibition and more cytotoxicity relative to sodium perchlorate. As the TAA and Median-Difference values decrease, their ranking scores also decrease.

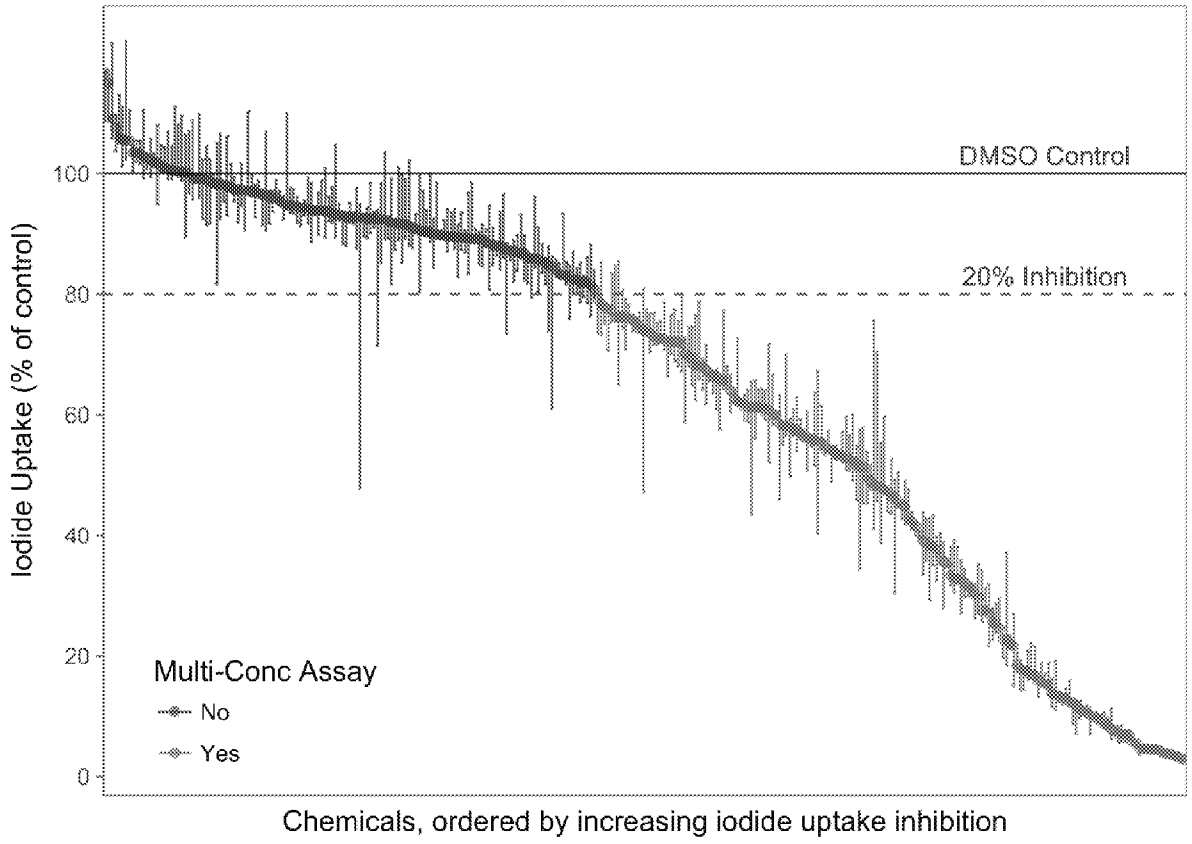

Fig. 2. Median and range of test chemical responses in single-concentration RAIU screening. Median response of each chemical is represented by the dot and vertical bar shows the maximal iodide uptake (top of the bar) and the minimum iodide uptake (bottom of the bar). The pink horizontal line represents the 20% inhibition threshold. 310 blinded samples were tested at maximum permissible concentrations (typically 100 μM). 169 chemicals (54.5%) were selected for multi-concentration testing based on a 20% inhibition activity threshold.

Fig. 3. (A) Responses of internal replicates in single-concentration screening. 12 chemicals in the ToxCast phase1_v2 library were replicated 2 or 3 times (supplied in 2 or 3 blinded chemical samples). Colors represent different chemicals, while shapes indicate different internally replicated samples for a given chemical. Since each sample was tested in three bioreplicates, each shape for a given chemical has three data points. Ten of the 12 replicated chemicals that gave >20% inhibition (pink horizontal line) in this single-concentration test were subsequently tested in multi-concentration format (Fig. 3B). **(B) AC_{50} of internal replicates in multi-concentration screening.** Each symbol represents one AC50 value obtained from one sample of the chemical tested in three bioreplicates in multi-concentration.

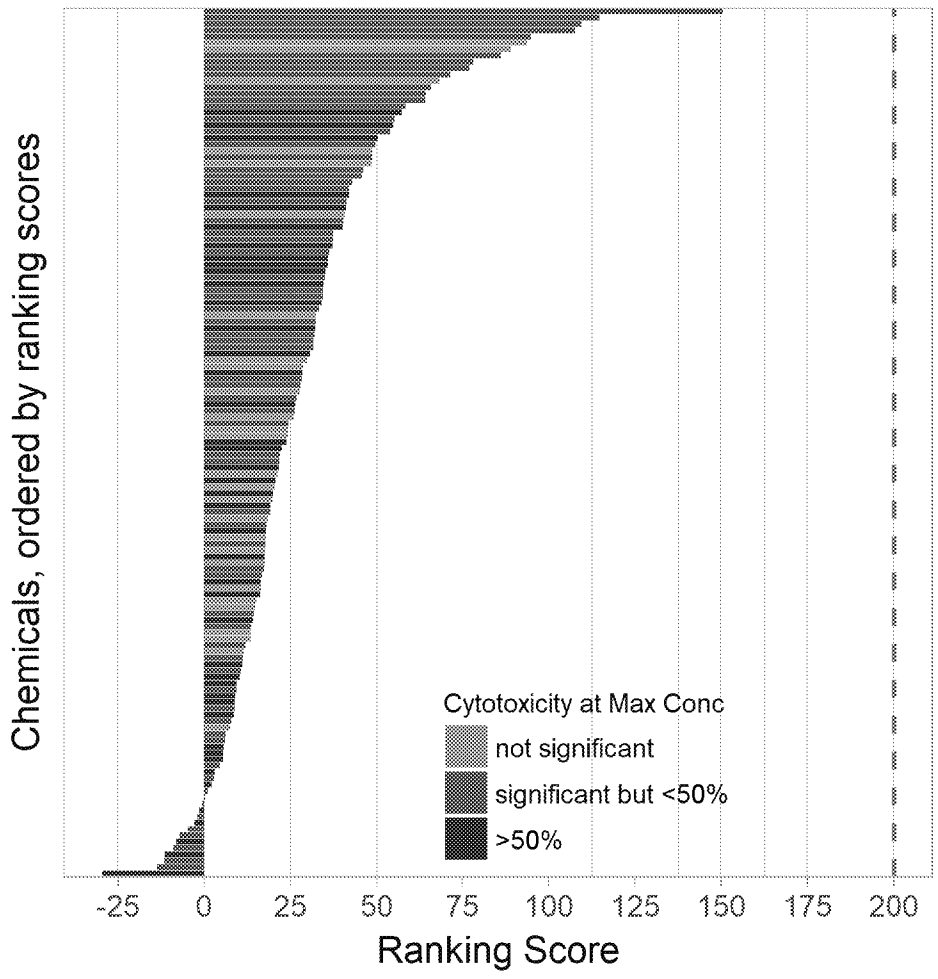

Fig. 4. Ranking scores for chemical samples tested in multi-concentration screening. Ranking scores were evaluated only if a chemical produced significant RAIU inhibition. Of the 169 chemical samples tested in multi-concentration, 32 did not show significant RAIU inhibition and were therefore excluded from the ranking analysis. The vertical dotted line is the ranking score of sodium perchlorate, which was used as the reference chemical in the ranking analysis. The ranking score of the 137 test chemical samples ranged from 150.41 to -29.52, with 4 having ranking score >100, 17 having ranking score between 50 and 100, and 116 having ranking score <50.

Cytotoxicity levels at the maximum testing concentration are indicated in colors shown. Of the 137 chemical samples that produced significant RAIU inhibition, 27 exhibited no cytotoxicity, 67 exhibited significant but <50% cytotoxicity, and 43 exhibited >50% cytotoxicity at the maximum concentration tested.

Table 2. List of test chemicals and screening results

Max Conc: the maximum permissible concentration tested in single-concentration screening. Serial dilution of samples for multi-concentration assay started with this concentration.

*: precipitate visually observed in the well of stock chemical plate.

Hit call: indicates whether chemical median RAIU inhibition was over 20% in single-concentration screening. +: yes, -: no.

AC_{50}: the AC_{50} value derived from multi-concentration dose-response curve.

$absEC_{50}$: the $absEC_{50}$ value derived from multi-concentration dose-response curve if the maximum inhibition achieved by the chemical was over 50%.

Cytotox-point: the log concentration where the chemical started to show significant toxicity ($absEC_{82.3}$).

	Chemical	CAS NO.	Max Conc(M)	Hit Call	AC50	absEC50	Cytotox Point	Ranking Score

Table 3. Summary of assay performance metrics for single-concentration and multi-concentration screening.

Assay[1]	CV of DMSO		Z' Score		AC50 of positive control[2]	
	mean±SD	range	mean±SD	range	mean±SD	range
Single-con RAIU	7.14% ± 1.56%	4.91% - 11.04%	0.77 ± 0.05	0.65 - 0.84	-6.44 ± 0.11	-6.56 - -6.06
Multi-con RAIU	8.61% ± 1.01%	6.70 - 11.50	0.72 ± 0.03	0.64 - 0.78	-6.38 ± 0.13	-6.57 - -6.04
Multi-con Cell Viability	5.42% ± 1.47%	2.80 - 9.53	n.a.	n.a.	-4.83 ± 0.12	-4.92 - -4.47

1: All metrics were calculated per assay plate (single-con: n=15, multi-con: n=54) and summarized separately for single-concentration and multi-concentration screenings.

2: AC50 of positive controls were calculated from the dose-responses of $NaClO_4$ and DCNQ for RAIU and cell viability assay respectively. Unit: logM.

n.a.: unable to calculate.

Table 4. Summary of normalized responses of control chemicals across all plates

Assay[1]	DMSO	2,4-D	DCNQ[2] (1E-4M)	$NaClO_4$[2] (1E-4M)	$NaNO_3$	NaSCN
single-con RAIU	100.63 ± 7.11	92.41 ± 4.24	n.a.	2.85 ± 0.36	81.25 ± 7.56	20.64 ± 1.12
multi-con RAIU	99.5 ± 8.28	90.86 ± 4.49	3.92 ± 3.37	3.28 ± 0.38	83.08 ± 7.17	24.69 ± 2.71
multi-con Cell Viability	100.92 ± 5.41	99.34 ± 3.21	3.72 ± 0.38	99.19 ± 4.69	98.95 ± 5.43	104.3 ± 3.98

Mean ± S.D.

n.a.: not available as DCNQ was not included in the single-concentration screening.

1. Data were calculated by collecting normalized response for each chemical from all assay plates. Values represent the percent of control activity. 2,4-D, $NaNO_3$, and NaSCN were at a concentration of 100 μM.

2. For DCNQ and $NaClO_4$, though they were included on each assay plate in six concentrations, only the responses from 100 μM concentration are summarized in this table.

NHEERL Fact Sheet

High-Throughput Screening of ToxCast Phase I Chemical Library for Sodium Iodide Symporter (NIS) Inhibitors

To be submitted to *Toxicological Sciences*

Jun Wang[1,2], Daniel R. Hallinger[1], Ashley S. Murr[1], Angela R. Buckalew[1], Steven O. Simmons[3], Tammy E. Stoker[1], and Susan C. Laws.[1]

Relevant National Research Program project/area of research: This paper supports Chemical Safety for Sustainability (CSS) research on High Throughput Toxicology, CSS 16.01, Task 2.1, *Development and optimization of vitro assays to address EDSP chemical activity toward targets affecting thyroid hormone,* Milestone 2. *Development of a Thyroid Sodium Iodide Symporter (NIS) Assay.*

Impact Statement: A novel screening approach has been developed to rapidly identify chemicals that can inhibit the uptake of iodide by the thyroid and disrupt the synthesis of thyroid hormones. This work addressed an urgent need and request from the Office of Coordination and Science Policy to develop *in vitro* assays to detect potential thyroid toxicants, and now provides a rapid screening approach that targets a key molecular initiating event, the uptake of iodide as mediated by the thyroid sodium iodide symporter (NIS), within the thyroid hormone pathway. This assay was used to screen the ToxCast Phase 1 chemical library. These findings for the Phase1-v2 chemicals can be utilized during an upcoming 2018 FIFRA Science Advisory Panel review to obtain recommendations and feedback for the Agency's Endocrine Disrupting Screening Program regarding the appropriate use of high throughput in vitro assays for the thyroid hormone pathway. This work is also of international interest because of the novel cell line created for this RAIU assay and its potential use for the development of an OECD test guideline.

Background: The Agency's Endocrine Disruptor Screening Program in the 21st century (EDSP21) aims to use high-throughput and computational toxicology methods to screen and prioritize chemicals for further testing based on their potential to affect estrogen, androgen, and thyroid pathways ([HYPERLINK "https://www.epa.gov/endocrine-disruption"]). The EDSP21 is currently limited in the ability to screen for chemicals that have the potential to affect homeostasis of the thyroid hormone signaling pathway. The development of the thyroid sodium/iodide symporter (NIS) assay is part of an effort lead by the Office of Research and Development to counteract this limitation by developing medium- and high-throughput screening assays that focus on molecular initiating events that could ultimately affect circulating thyroid hormone levels. To maintain sufficient concentrations of circulating thyroid hormones, the thyroid requires the active uptake of iodide as mediated by the NIS. Monovalent anions, such as the environmental contaminant perchlorate, have been well characterized as competitive inhibitors of NIS-mediated uptake of iodide, but limited information exists for more structurally diverse chemicals. The development of a screening approach to identify NIS inhibitors will enable the rapid prioritization of chemicals currently under the Agency's purview for further testing as potential thyroid disrupting activity.

Study Description: A novel cell line stably expressing human sodium iodide symporter (NIS), hNIS-HEK293T-EPA, was developed for use in a screening approach to identify chemicals that inhibit NIS-

mediated radioactive iodide uptake (RAIU). For this RAIU assay, NIS-expressing cells were exposed to ^{125}I in the presence of serial dilutions of each test chemical ranging from 0.001 – 100mM. NIS-mediated ^{125}I uptake was then quantified to identify test chemicals that inhibit this action, indicated by decreased intracellular ^{125}I uptake relative to controls. Experiments were conducted to determine optimized assay conditions and to demonstrate assay performance using a set of reference chemicals containing known inhibitors of NIS-mediated iodide uptake and known inactive chemicals. This assay was used to screen chemicals in the ToxCast Phase 1_v2 chemical library for the potential to inhibit thyroid hormone synthesis by disrupting the NIS. A cell viability assay was subsequently conducted for each chemical used in the RAIU assay. A ranking system was developed based on the multi-concentration responses in the NIS assay and the confounding cytotoxicity for the 293 chemicals to inform the prioritization of the chemicals for secondary testing.

Research Results: Results from this study demonstrated that the NIS-mediated ^{125}I uptake assay is accurate, reproducible, and reliable for screening large libraries of chemicals. The ranking scores were assigned to chemicals which inhibited the NIS activity by more than 50% and allowed selection of chemicals with the potential to interfere with thyroid synthesis. Based on the ranking of the positives in the multi-concentration testing, approximately 21 of the 293 are being tested in follow-up secondary assays to confirm inhibitory activity.

Conclusion: The use of hNIS-HEK293T-EPA cells in the NIS-mediated iodide uptake and cell viability assays provide the U.S.EPA with a rapid approach for identifying chemicals that have the potential to disrupt a key molecular step essential for the synthesis of thyroid hormones. The screening and ranking of 293 chemicals in this study represents the first large scale effort to investigate NIS as a molecular target of environmental chemicals that covers a broad spectrum of structural and toxicological properties. These data can inform the prioritization of chemicals for secondary testing, and support the needs of the Endocrine Disruptor Screening Program for additional high-throughput in vitro assays to screen chemicals for interaction with more molecular targets that can disrupt normal thyroid hormone signaling. This assay and ranking approach can now be used for screening other larger chemical libraries such as the ToxCast Phase1_v2, Phase 2, and E1K libraries.¶

Subject: RE: Perchlorate FRNs and Transmittal

Dan,

I'll do an initial review of the FRNs this morning. In the meantime, we need to draft an action information one pager to submit to OW as soon as possible (see template attached). The one-pager will suffice for both FRNs.

Thx,
Steph

Dan,

Attached are my comments on the 2 FRNs and memo. I'm including Stephanie on this email so she can do a preliminary review to expedite things later on.

For the memo, you will need 2; one from Eric to Peter and another from Peter to Mike – the content will be similar.

Good afternoon Lisa and Ryan,

Thank you both for chatting earlier. Please see the message from Greg Miller below. I suspect that Crystal, Eric and Jennifer will also want to review and provide feedback. To facilitate those reviews in time, here is what I propose in terms of next steps:

- Provide staff-level (SRRB/TAB) comments to Lisa and Ryan by **COB Tuesday 6/9**
- Lisa and Ryan to review and provide comments to Crystal and/or Eric by **Tuesday 6/16**
- Transmit consolidated SRMD comments to Jennifer by **Tuesday 6/23**

I'll be happy to coordinate and consolidate comments during this process. Please let me know if you have any questions or concerns, and thank you in advance for your time on this review.

All the best,

Hi Alex,
Attached you will find the PFBS Toxicity Assessment that is being shared for internal EPA review through the usual IRIS process. I'm sharing these documents with you as the point of contact for OGWDW. Jennifer McLain has flagged the thyroid (email below) as an area of concern given the perchlorate NPDWS rule withdrawal currently under review at OMB. Please coordinate your response with the perchlorate team in OGWDW (Sam, Rajiv, Lisa) as you draft your comments. Comments are due to ORD by 6/30, but if you could have your comments to me by 6/25, I will combine the OST and OGWDW comments into one document as was requested.

Thanks!

Hello all,

You are receiving this email because you have been identified as your office's point of contact for review of toxicity assessments in general and/or as the PFAS point of contact. If this has reached you by mistake and there is another individual that should be the point person, please let me know as soon as you can.

This email is to initiate the internal agency review of the revised PFBS toxicity assessment. Shortly, you will be granted access to the SharePoint site (see link below) so that you will be able to obtain the PFBS draft toxicity assessment as well as the Response to peer review comments document. Please feel free to circulate the materials within your respective

office, we just ask that as the points of contact, that you compile and upload one set of comments from your respective office. We request that you post comments to the SharePoint site by **COB Tuesday, June 30th**.

https://usepa.sharepoint.com/sites/ORD_Work/pfas_toxval_internal_review/SitePages/Home.aspx

We appreciate your feedback. Please let me know if there are any questions.

Thank you!

Conference Extension: Ex. 6 Personal Privacy (PP)
Participant Code: Ex. 6 Personal Privacy (PP)

Hypochlorites team,

Since our 1-24-17 meeting with the Chlorine Institute (CI), CI has submitted comments on chlorate and perchlorate that may have an impact on our path forward. We've also identified best management practices from OW, AWWA, and the Chlorine Institute. Our next meeting with CI is on Thursday, 3-23-17.

By the end of this meeting, we want to:

1.) Review comments from CI
2.) Review the BMPs comparison document, are there any BMPs we wouldn't consider?
3.) Finalize agenda for 3-23-17 meeting

Please see the following documents:

1.) CI Comment Documents
    a. CI Comment Letter on Perchlorate: reaffirms that AWWA reports predate 1-1-13 implementation of NSF/ANSI Standard 60 and don't reflect perchlorate minimization improvements, perchlorate levels are likely more from naturally occurring chlorate, and a 2016 isotope study (also attached) provides compelling evidence that natural perchlorate is the dominant source of human exposure.
    b. 2017 CI Comment Letter on NRDC Recommendations: CI negates use of pH as a BMP, and various other non-BMP related issues.
2.) Hypochlorite Best Management Practices 3-17-17: compares BMPs from AWWA, CI, and OW.
3.) Agenda for OPP-CI Chlorate-Perchlorate Follow-Up Meeting 3-23-17 (they will be calling in), this agenda is a draft.

Thank you all!

Clif,
Did you send me the electronic version of your briefing? I couldn't find one so if you would please send that to me I'd appreciate it. Also as far as next steps and timing I wasn't sure if you needed or were waiting for direction or input from Lisa on how Cadmus should proceed with updating the occurrence doc? It might be good to set up a time to go over the briefing with Lisa and Dan so they can understand any issues or concerns you might have on updating the occurrence doc – I would like to be included but I think it might be difficult for me to relay any issues or provide you with specific recommendations based on my limited involvement on this project.

Thanks,

TABLE OF CONTENTS

[TOC \o "1-3" \h \z \u]

I. BACKGROUND

The U.S. EPA's Office of Water is in the process of developing National Primary Drinking Water Regulations for perchlorate under the Safe Drinking Water Act. In 2012, EPA submitted a white paper *Life Stage Considerations and Interpretation of Recent Epidemiological Evidence to Develop a Maximum Contaminant Level Goal for Perchlorate* (U.S. EPA, 2012) to the Science Advisory Board (SAB) for review. The white paper presented scientific information published since the National Research Council (NRC) released their 2005 Report "Health Implications of Perchlorate Ingestion" and described how EPA derived a range of Maximum Contaminant Level Goal (MCLG) values for life stages of concern. In their 2013 report, the SAB concluded that EPA should: 1) consider exposure to the following sensitive life stages: the fetuses of hypothyroxinemic pregnant women and infants exposed to perchlorate through either water-based formula or the breast milk of lactating women, and 2) derive the MCLG using a physiologically-based pharmacokinetic/pharmacodynamic (PBPK/PD) model to account for exposure differences and biological differences across life stages, including sensitive life stages. Specifically, the SAB found that the 'default algebraic approach provides limited ability to address the various exposure and biological factors affecting sensitivity to perchlorate at different life stages.' The SAB concluded that from a scientific standpoint it would be more appropriate to base the MCLG derivation on the perchlorate mode of action, using PBPK/PD modeling to relate perchlorate concentrations in drinking water to biological effects rather than the default approach.

The SAB report referenced a report by Lumen et al. (2013) on the effect of perchlorate on thyroid hormone perturbations for pregnant mothers and fetuses, as well as their work to extend a physiologically-based pharmacokinetic/pharmacodynamic iodine uptake inhibition (PBPK/PD-IUI) model with links to serum thyroid hormone levels, as a starting point for EPA's efforts.

The new modeling effort presented here integrates the previous EPA PBPK model (2009) for perchlorate with the model developed by Lumen et al. (2013) for pregnant mothers and fetuses (humans) and iodide models developed by Fisher et al. (2013) for lactating rats and Fisher et al. (2016) for lactating mothers and nursing infants (humans). The model has been subjected to a quality assurance (QA) review that was conducted by Oak Ridge National Laboratory (data and parameters used) and Pacific Northwest National Laboratory (model code). The Biologically Based Dose Response (BBDR) model predicts thyroid hormone perturbations for lactating mothers, breast-fed infants and bottle-fed infants resulting from exposure to perchlorate under different dietary iodine intake levels. EPA is relying on the Lumen et al. (2013) model, peer reviewed and published previously, to predict effects for pregnant mothers and fetuses. It is important to note a modification to a key parameter was made (Michaelis-Menten constant for the sodium-iodide symporter for perchlorate, Km) and the thyroid hormone predictions were adjusted for pregnant mothers and fetuses in the model report under review.

EPA is seeking comments on the scientific rigor of the model for evaluating the effects of perchlorate on thyroid hormones in lactating mothers, breast-fed infants and bottle-fed infants under different iodine intake levels. EPA is providing access to the model program code and all necessary files to facilitate use of the BBDR model by peer reviewers and the public. EPA

expects that those reviewers with the appropriate software and expertise will be able to replicate the results described in the BBDR model report. After completing development of the BBDR model in the acslX software, the U.S. EPA created a copy of the model that can be run in the alternate software, R. The report URL with links to the code (acslX and R versions for both the pregnancy and infant/lactation models) is: [HYPERLINK "https://hero.epa.gov/hero/index.cfm/reference/details/reference_id/3352518"]

Note that the model is calibrated and expected to be valid for conditions where feedback regulation due to variations in thyroid-stimulating hormone (TSH) levels is minimal, so all charge questions regarding the model are for that range.

In March 2016, the Agency invited the public to nominate scientific experts to be considered as panelists for peer review of the draft model and accompanying report. In June, EPA announced that to achieve efficiency it was expanding the scope of the peer review to include draft approaches for application of the model to inform the development of a perchlorate MCLG. EPA has since reevaluated the review process in response to concerns that a simultaneous review of approaches for application of the model to develop a perchlorate MCLG would not allow for prior consideration of peer reviewer comments specifically on the model.

Therefore, EPA seeks public comment and peer review on the modeling approaches and the ability of the model to predict outcomes that could potentially be used to inform the derivation of an MCLG. EPA intends to seek input on the application of the model for developing approaches for a perchlorate MCLG determination at a later date. Future efforts will include discussion of health endpoints and response levels that are most appropriate to base the MCLG determination.

II. CHARGE TO REVIEWERS

1. Model structure: Please comment on the following aspects of the Biologically Based Dose Response (BBDR) model structure and integration of the submodels for iodide/thyroid hormones and perchlorate for each of the life stages of focus (e.g., lactating mother, breast-fed infant, and bottle-fed infant):

    a. Does the developed model structure adequately and accurately describe the physiology and kinetics of iodine, thyroid hormones, and perchlorate during different life stages specified above? Please specifically note the strengths and weaknesses of the model structure for each life stage. Please also suggest approaches to address identified weaknesses in the model structure.

    b. Are the physiological and kinetic parameters for iodine, thyroid hormones, and perchlorate for these life stages supported by the published sources for those parameters or data used to identify parameters via calibration? Please identify any critical data gaps and suggest additional data or parameter (values) to these proposed model parameters to address identified gaps.

    c. While the model predicts the dose-response for fetal thyroid hormones, a reference range for the fetus was not identified. Are there additional data, parameters, or (sub)models available that might be useful for evaluating fetal effects? If not, can the predictions for thyroid hormone changes in the pregnant mother be used as a measure of potential fetal effects?

2. Modifications to existing models: EPA has modified one parameter in the 2013 Lumen et al. model: KM_TPNG, the Michaelis-Menten constant for the sodium-iodide symporter for perchlorate based on Schlosser (2016), and a second key parameter in the 2009 USEPA/2007 Clewell et al. PBPK models: VMAXC_MKP, the maximal velocity for perchlorate transfer to breast milk from those components in the USEPA 2009 models. These two parameters affect perchlorate transport from the mammary plasma to breast milk (VMAXC_MKP) and the strength with which perchlorate inhibits iodine transport by the sodium-iodine symporter (KM_TPNG). Detailed information on the assumptions and data considered in making these changes are provided in the report appendices. Are the changes scientifically supported and reasonably estimated?

3. Model calibration and sensitivity analysis: Please address the strengths and limitations of the model calibration process and the strengths and limitations of the data used for model calibration and evaluation. Identify any additional literature, data, or peer reviewed models that EPA should consider to address identified limitations.

    a. Specifically, is the model calibration and evaluation adequately compared with what is reported in the literature for iodine and perchlorate concentrations in urine, and breast milk and thyroid hormone plasma concentrations under different iodine intake and perchlorate exposure scenarios? Please identify additional studies that would support model calibration that strengthen the proposed model.

b. Are the influential parameters identified in the local sensitivity analysis for total thyroxine (T4) and free thyroxine (fT4) plasma concentrations consistent with known biology? Are there critical data gaps for the influential parameters, which would impact the thyroid hormone predictions? If gaps are identified, please provide approaches that would improve thyroid hormone predictions.

c. Does the proposed model provide the appropriate level of precision and substantiated support for this approach? Please identify any additional limitations of the model's applicability?

4. Hypothyroxinemic reference levels and model predictions: The SAB (2013) recommended that the EPA focus the application of BBDR modeling on the condition of hypothyroxinemia, in which circulating levels of free thyroxine (fT4) are reduced below the normal ("reference") range, but with normal levels of thyroid stimulating hormone (TSH). While the mode of action (MOA) for perchlorate is well described, a defined set of quantitative definitions for reference ranges for hypothyroxinemia during pregnancy or lactation and in infants is not available. For interpretation of the BBDR model, EPA developed a normalization procedure to derive hypothyroxinemia reference intervals and to control for the expected differences between literature results and model predictions.

   a. Please comment on the hypothyroxinemia reference ranges derived for pregnant mothers, fetuses, lactating mothers, breast-fed infants and bottle-fed infants. Is the assumed range between the 2.5^{th} and 10^{th} percentile of the fT4 distribution reasonable? Is it supported by the available data? Has the derivation of the reference ranges, including the normalization process, been appropriately described and supported in the model and the report?

   b. Model predictions for zero intake of perchlorate indicate the range of iodine ingestion for which these life-stages are expected to be euthyroid vs. hypothyroxinemic. Are these predictions reasonable and have they been appropriately described and supported in the model and the report?

   c. Based on the perchlorate level at which each life stage is predicted to become hypothyroxinemic (for a given iodine ingestion rate), it appears that the lactating mother is more sensitive than the breast-fed infant for PND 30-90. In part, this occurs because breast feeding reduces the iodide available for the maternal thyroid. Are these predictions reasonable and have these predictions been appropriately described and supported in the model and the report?

5. Robustness of model predictions and sensitivity at lower perchlorate dose levels: The dose-response predictions from the BBDR model predict levels of fT4 for:
   a) The pregnant mother and fetus at GW40 (Fig. 10);
   b) The formula-fed infant with fixed (Fig. 11, 7 and 30 day infants) and variable (Fig. 12, 7 through 90 day infants) iodine levels in their formula; and
   c) The breast-fed infant as a function of maternal perchlorate exposures and iodine ingestion (Fig. 13, 7 through 90 day infants).

For each of these subgroups, please characterize the extent of uncertainty along the dose-response curve. In particular, is the level of uncertainty acceptable at lower dose levels of perchlorate (e.g., at or below 4 µg/kg/d) and higher levels of iodine intake (e.g., 150 µg/d) for each of these subgroups (left upper corner of the dose-response curves)? Should EPA assume that the model becomes more uncertain with rising perchlorate dose levels and declining iodine ingestion, i.e., as model predictions for fT4 approach and move through the range of hypothyroxinemia. (It should be noted that calibration of the iodide and thyroid hormone sub-models used data for populations with higher iodine intake and background exposure to perchlorate.)

6. Empirical functions to predict thyroid hormone levels: The pregnancy model (but not the lactation/infant models) uses empirical functions to make urinary clearance of iodine and metabolic degradation of T3 dependent on the iodine ingestion level, in order to predict observed nonlinearity in the relationship between thyroid hormone levels and iodine intake. Does this use of empirical functions result in predicted outcomes or trends that are not plausible for serum thyroid hormones, particularly fT4?

7. Characterization of model predictions: The pregnancy and infant/lactation models were developed to specifically consider the range of iodine ingestion and thyroidal uptake where TSH is expected to stay in its normal range (i.e., they do not account for HPT feedback control). Do the models represent a reasonable effort to describe the relationships between iodine intake, perchlorate exposure and thyroid function? Are they sufficiently specific to predict perchlorate-induced changes in thyroid hormones in these life-stages over the range indicated? Please characterize the robustness, precision and sensitivity of the models for the ability to extrapolate changes in T4 associated with perchlorate exposures over the range from low exposures (less than 1 µg/kg/d) to higher levels which the model and analysis predict to be hypothyroxinemic.

III. GENERAL IMPRESSIONS

Hugh A. Barton, Ph.D.

Overall this is an extensive systems model that appears to have been carefully and thoroughly developed using available scientific information. The report is generally clear and the logic of the decisions presented seems reasonable. It is difficult to evaluate a model of this complexity by reading the report. This reviewer did not access the model, but in my experience it would take considerable time working with a model of this complexity to develop perspectives on its strengths and limitations.

Claude Emond, Ph.D.

This peer review is part of the U.S. Environmental Protection Agency's (EPA's) National Primary Drinking Water Regulations (NPDWR) initiative for perchlorate a water contamination. This review is also the second phase of Science Advisory Board (SAB) 2013, in which a peer review recommended that EPA should use a physiologically based pharmacokinetic (PBPK) model published earlier, but should integrate the iodine description, including the hormones T3 and T4, to study the hypothyroxinemia and health effects after exposure to perchlorate during lifetime and windows of sensitivity. Two models are presented here 1) mother and fetus PBPK, and 2) mother and infant. Both integrate the previous model of perchlorate that was published and used for the SAB assessment in 2009. These improving versions integrated the iodine/thyroid pharmacokinetic for different stages of life, including the fetus, newborn until 91 days, pregnancy or no pregnancy, and lactation. This report is very well described with transparency and very well referenced for part of the code model, but there is a little fogginess for the m files. The methodology that was used reflects the state-of-the-art employed in pharmacokinetic modeling. I agree that this model is a good start to better understand the mode of action, including the limiting step that we know from literature today. The authors who developed this PBPK model are very knowledgeable in the design of PBPK models; therefore, I am very confident that the design, along with the review that I performed. The combined PBPK model for iodine/perchlorate exposure following sensitive lifetime windows can be used for human risk assessments of health, based on the limitations suggested by the authors. It is interesting to note that the authors also reported a limitation of the PBPK model regarding the range of dose and the windows of sensitivity. I agree with the authors' conclusions regarding the predictability and the limitations of this model. It is important to remember that these models are described for human exposure, which should drastically reduce the uncertainty of the point of departure (POD) used in risk assessment. In addition, the simulations reviewed in this report reproduced relatively well the biomonitoring data published.

Dale Hattis, Ph.D.

Although I have some concerns about the parameterization of the models, my most serious problems with the analysis relate to the choice of population to be modeled and the endpoints that were made the focus of the analysis.

Briefly, in focusing on thyroid hormone changes, the authors have neglected the prime effect of ultimate interest—changes in cognitive development measured as IQ. The latter will need to be a key focus in the mandated "Risk Reduction and Cost Analysis (HRRCA)" referred to in the introduction. IQ differences are readily subject to the comparative economic analysis needed for an HRRCA, whereas it will be difficult to quantify the independent value of thyroid hormone changes themselves for juxtaposition with compliance and other costs of alternative regulatory actions to change exposures. Moreover, studies in the very recent literature, such as those from Holland, provide an excellent basis to quantify effects of both thyroid hormone changes[1] and perchlorate itself[2] during pregnancy on cognitive function as reflected in the IQ measured in the offspring.

Additionally, the focus on modeling of changes in thyroid hormone levels has led the authors to focus their analysis on lactating mothers and breast- and formula-fed infants after birth. This neglects the population groups that are known to be most sensitive to the effects of iodide and thyroid hormone action—women in the first pregnancy trimester, and possibly even the first month of pregnancy before the women may even be aware that they have conceived.[3,4,5]

The Specific Observations on Model Report, at the end of these comments, provides abstracts of recent papers that I think should be used in crafting a better analysis more relevant to EPA's needs in choosing policies to change the existing exposures to perchlorate in the United States.

Angela M. Leung, M.D., M.Sc.

The objective of this proposed BBDR model was to assess the potential adverse thyroidal effects of perchlorate exposure, based on the physiologic kinetics of perchlorate and iodide action on serum free thyroxine (FT4) concentrations among lactating women, their breastfed infants, and

formula-fed infants. Calibration of the model was achieved using published levels of perchlorate and iodine found in breastmilk, maternal urine, and infant urine, and of serum FT4 concentrations in each of these three lifegroups. The model's dose-response relationships between perchlorate exposure and serum FT4 concentrations are reported for various perchlorate exposure and daily dietary iodine intake levels.

The primary endpoint was hypothyroxinemia, defined as the 2.5-10th percentile of serum FT4 concentrations, among lactating women, breastfed infants, and formula-fed infants. Overall, there is less robust evidence in the literature to support the adverse health implications of mildly low serum FT4 concentrations among infants regarding future neurodevelopmental outcomes, compared to the same for pregnant women, in part due to complete reliance of the fetus on adequate maternal iodine and thyroid hormone levels during the first half of pregnancy and the crucial period of rapid neurodevelopment during this time.

The second concern is in regards to the interpretation of published data regarding iodine and perchlorate levels in breastmilk, maternal urine, breastfed infant urine, and formula-fed infant urine; and serum FT4 concentrations in lactating women, breastfed infants, and formula-fed infants. The accuracy of calibration of the model is limited by several issues, including: 1) the use of several relatively small studies containing limited datapoints, particularly for maternal serum thyroid hormone concentrations, 2) the absence of serum thyroid autoantibody data that can influence serum thyroid hormone concentrations, 3) the problems of extrapolation of pregnancy thyroid hormone physiology for the lactation model, 4) the absence of data regarding the timing of dietary iodine intake in relation to breastmilk iodine concentrations in the current available literature, and 5) the inference of analyte and hormone measurement values in the submodels that each assume an exclusive source of infant iodine nutrition.

Finally, the model does not take into account likely coexposures from other environmental and dietary goitrogens, including thiocyanate and nitrate, and it does not consider the dynamics of the hypothalamic-pituitary-thyroid (HPT) axis that is able to respond acutely to even small changes of iodine availability and peripheral thyroid hormone concentrations. Given all of the above and as summarized in much greater detail below, the model presents an estimate of the potential thyroidal effects resulting from perchlorate exposure, but is likely still fairly inexact.

For the record, I am a clinical endocrinologist with research interests in iodine nutrition and environmental thyroid disruptors during pregnancy and lactation, but do not have sufficient background and expertise in modeling to comment on the charge questions that specifically address those aspects of the model.

Michael H. Lumpkin, Ph.D., DABT

The developed model structure adequately captures the known biological processes acting to exchange iodine, TH, and perchlorate across tissue interfaces and transport these molecules across tissue systems and out of the body. The report describes well the representation of the biology in the mathematical model structure. The report describes in detail the selection of data that serve as the basis of model parameter values for the various life stages. This includes the consideration of data published or made available since publication of the foundational BBDR

and PBPK models for perchlorate. Historically, the use of maternal internal dosimetry and pharmacodynamics have been accepted as adequate surrogates for fetal internal doses or effects, are preferable to using maternal administered dose for extrapolation to fetal effects. The justifications for modifying the saturable NIS physiology and NIS transport of iodide and perchlorate into breast milk using more robust data are sufficiently supported in the model report. Given the model structure changes required to align the perchlorate PBPK and iodine BBDR models, the need to revisit the model's fidelity to replicate the Greer et al. data was warranted. The model performance across the various represented life stages appears to be robust for low perchlorate exposures and iodide intake levels resulting in thyroid hormone levels above the 10^{th} percentiles for the reference ranges. Although the model is restricted to represent limited thyroid hormone homeostasis, it represents a plausible and technically justified approach to defining the perchlorate dose-response across a narrow exposure range. An informative analysis would be to further parameterize the NIS transport parameters to adjust the effect of NIS inhibition as T4 levels approach the hypothyroid condition. Using this simple approach, the effect of compensatory upregulation of NIS activity can be explored and evaluated as plausible or not.

Elizabeth N. Pearce, M.D., M.Sc.

The clarity of the writing could be improved; the document is complex and hard to follow. Many of the figures are challenging to interpret: both duplicating information in tables and providing color figures would be helpful. A single glossary including a list of all of the variables as well as the list of abbreviations would be useful for reference.

A more detailed rationale for the choice of hypothyroxinemia as the primary outcome of interest could be provided in the Introduction. This is fundamental for understanding the document which follows.

The literature search, as described on page 22, should be updated with clearly defined search parameters and methodology for study evaluation and selection. It is noted that after 2013 additional papers "later identified as potentially relevant" were added, but there does not appear to have been any formal approach to follow-up literature searches. It would be helpful to broaden the search by considering databases other than PubMed, to institute a systematic framework for study inclusion and exclusion and for evaluating study quality, and to update formal searching. Strategies for these methods have recently been described in an environmental health context (e.g., Morgan RL, Thayer KA, Bero L, et al. GRADE: Assessing the quality of evidence in environmental and occupational health. Environ Int. 2016 Jul-Aug;92-93:611-6). There has been a great deal of new literature since 2013 with relevance to effects of perchlorate on thyroid function and other outcomes in epidemiologic studies; many new pregnancy cohorts in the literature have described thyroid function reference ranges; and there are many new observational studies regarding effects of maternal hypothyroxinemia on child developmental and other outcomes. Some of these new studies could provide support for the selection of hypothyroxinemia as the outcome of interest, and many could provide valuable data for further validating models.

Please note that my expertise is in clinical thyroidology and iodine metabolism. I do not have expertise specifically in the development or use of BBDR modeling. While I comment below on many of the assumptions that went into the models and the data used to validate them, I will need to defer to other peer reviewers with modeling expertise regarding the model code.

Stephen M. Roberts, Ph.D.

It is apparent that a great deal of work has been conducted to develop a proposed BBDR model that is responsive to recommendations by the SAB Perchlorate Advisory Panel. I found the information presented to be accurate, although in some instances incomplete. While the report may serve the purpose of documenting steps taken to create the model, it lacks clarity of presentation in a number of important areas. Problem areas identified include:

1. Confusing presentation. For example, it is not clear from the document whether pregnant women are included in the model described here or are a separate model (modified Lumen et al. model?). Much of the language seems to exclude pregnant women from the model being presented (e.g., "Model development efforts focused on: 1) the lactating mother; and 2) the breast-fed and formula-fed infant for the postnatal period from postnatal day PND) 7 to 90." (pg 6) and "The new BBDR model is intended to predict and evaluate the potential combinatory effects of iodine nutrition and exposure to perchlorate on thyroid function in the infant and lactating mother." (pg 13)) although some modeling results for pregnant women are presented in the report (pg 70). Other examples of sections in the document that are difficult to follow or confusing are included in the responses to charge questions below.

2. Missing explanations/justifications. Although explanations are provided for model inputs, there are important decisions for which no explanation is provided. An example is the decision to model the thyroid hormones in the pregnant woman near term. While normal neurodevelopment requires adequate thyroid hormone throughout gestation, the fetus is particularly sensitive during early gestation. This gives rise to the obvious question of why near term was the time point chosen for modeling. Is it assumed to be representative of earlier gestational time points? Is it, in the opinion of the EPA, in fact the most sensitive time point? Was it simply a matter of the availability of better data for modeling at this time point? Some explanation is needed.

3. Poor graphics. Many of the graphs present multiple plots that are difficult to distinguish.

In addition to describing what is included in the model, it would be useful to also discuss (perhaps in an appendix, companion memo, or some other format), what was not included and why. An example might be a probabilistic treatment of inputs and model output. There can be a number of legitimate reasons why possible inclusions or refinements in the model were not chosen for this iteration of model development, including limitations in time, resources, and/or data availability, or their addition was thought unlikely to significantly improve the model. This is perhaps unusual, but a candid discussion, however brief, would be helpful in understanding the EPA's view why this model, at this time, is considered appropriate.

Joanne F. Rovet, Ph.D.

EPA has requested comments on the scientific rigor of a BBDR model for predicting thyroid hormone perturbations for lactating mothers and breast-fed and bottle-fed infants following their exposure to perchlorate at different levels of dietary iodine intake. This model is an expansion of the one described in a peer-reviewed paper by Lumen et al. (2013) predicting effects for pregnant mothers and fetuses. The current model seeks to address the main recommendations of a Science Advisory Board-Perchlorate Advisory Panel (SAB-PAP) for developing a maximum contaminant level goal or safe perchlorate exposure level for the following sensitive life stages: fetus, pregnant woman, and breast- or formula-fed infant. The PAP group considered these life stages particularly sensitive to perchlorate effects since they reflected stages when the greatest harm from an insufficiency of thyroid hormone would occur to the developing human brain. The pregnant woman was included as a sensitive life stage since she was considered a surrogate for providing thyroid hormone prior to onset of fetal thyroid function when thyroid hormone is critically needed for fetal brain development; the pregnant woman was also considered a supplementary or complimentary source of thyroid hormone in later gestation prior to full function at term.

The current modeling process claims -- for the first time -- to offer a BBDR approach that calculates the adverse consequences of a particular level of perchlorate exposure. Perchlorate is a potent inhibitor of iodide, a key component of thyroid hormone, and is taken up by the maternal, fetal, or infant thyroids or the lactating breast. The model's authors have conceived a reasonable, relatively simple model of biological action and from the literature, have provided an extensive set of realistic parameters and metrics to track the biological actions. These ultimately determine when an infant or lactating mother will become hypothyroxinemic from a specific level of perchlorate in a specific iodine environment. Authors are to be commended for their thorough, systematic, and ambitious approach to capture the situation, particularly on the perchlorate-iodide side of the equation.

However, I have several reservations about the approach and certain assumptions, leading me to sense some naiveté and perhaps lack of understanding on the part of the modelers. First, I am not convinced that the fT4 range used to mark hypothyroxinemia is appropriate and, rather, is too lenient. There is no evidence of what constitutes hypothyroxinemia in an infant and what the exact cut-offs are; these are all based on values from pregnant women. I am also concerned that the thyroid-side of the system may be too simplistic and not correct; the HPT axis, for example, is not modelled. Perchlorate contamination in the water used to prepare formula is not included in the model despite being mentioned in the SAB-PAP (2013) report. The key critical stages set out in the latter, namely pregnant mother and fetus, are for reasons that I do not find convincing disregarded, even though these stages are included in the title and extrapolated in the results; however, I am not sure how this was done. Also, the primary downstream endpoint, namely altered brain development and associated cognitive abilities and behavioral factors, is never considered. The modelling itself is based on old references, which I find concerning in light of the many papers on maternal thyroid dysfunction in pregnancy that have been published in recent years. The process whereby the ultimate 6 papers were selected from the final 62 is not specified. I also would have liked a better description of each of the papers, even if in the Appendix, than the current summary in Table 2. In addition, the model does not account for

other contaminants such as thiocyanate and nitrates that similarly interfere with iodide uptake. The data for the lactating women assume a common start point with regard to iodide sufficiency; however, no attempt is made to examine factors in pregnancy that might also contribute to iodide differences in the breast such as salt intake, particularly iodized salt; dietary factors (kelp, fish, amount of drinking water); use of iodine-containing prenatal vitamins and other supplements; amount of weight gained by mother and size of baby.

Additionally, I was disappointed in the lack of transparency on derivation of results and found the results section, especially the figures, which are relatively poor quality, hard to interpret. The latter aspect is particularly disheartening given the beautiful graphics supplied by "R". To improve clarity, all figures also would have benefited significantly by better more extensive figure captions. Overall, I found the Results section very poorly organized and hard to follow, very preliminary and rushed, almost as a first draft. It was not clear to me how data on pregnancy and fetal development were derived. While somehow, I think this is extrapolated back to birth at 40 weeks' gestation, to me this does not adequately represent the period of pregnancy nor fetal life. The writing generally carried a degree of vagueness (e.g., "adequate" p. 60; "within the range" p. 62) and lack of precision and it was generally quite difficult to follow the information in the figures from the corresponding text. Finally, as there was no proper ending to the report and no conclusions or take-home message, I was left with a sense of confusion – and disappointment. This was especially apparent in the Local Sensitivity Analysis that lacked proper discussion. This report should be readily understandable by persons of all disciplines; I sense it is written mostly for modelers and sometimes in modelling lingo.

IV. RESPONSE TO CHARGE QUESTIONS

Question 1. Model structure: Please comment on the following aspects of the Biologically Based Dose Response (BBDR) model structure and integration of the submodels for iodide/thyroid hormones and perchlorate for each of the life stages of focus (e.g., lactating mother, breast-fed infant, and bottle-fed infant):

Question 1A. Does the developed model structure adequately and accurately describe the physiology and kinetics of iodine, thyroid hormones, and perchlorate during different life stages specified above? Please specifically note the strengths and weaknesses of the model structure for each life stage. Please also suggest approaches to address identified weaknesses in the model structure.

Hugh A. Barton, Ph.D.

This question really requires expertise in thyroid hormone, iodine, and perchlorate biology. As an expert in modeling I cannot directly comment on how well the model structure captures the biology.

One question raised in the public comments was whether there were regulatory processes that would occur at low iodine and T4 levels, such as induction of NIS. It would be good to know whether there is information on this point.

Another question raised in public comments about the model structure was the change from a three compartment thyroid to a two compartment description. From the text on p 30, it appears that having a consistent structure in the fetal (Lumen et al., 2013) and the infant models might have been part of the rationale for this change. This could be clarified and perhaps some information provided as to the value provided by the three compartment description in previous modeling by comparison with this two compartment approach; was this a model simplification that had relatively modest impacts on model behaviors or was this a more substantial change or is this not known?

Claude Emond, Ph.D.

Strengths:

- The way in which the authors describe the codes in acslX in the 2 models was relatively easy to follow and well referenced for the CSL file.
- Comparing the simulation to the biomonitoring data from the literature, we can say that the predictability of the model is acceptable.
- The confidence in the models should be qualified by a medium that is inside the limitation of the model.

Weaknesses:

- The conceptual PBPK model structure (Figure 3) does not describe what the codes represent. The model codes describe kidney, liver, mammary

gland, GI_{tract}, skin, and thyroid and so on. It should be easier to incorporate these compartments inside of Figure 3.

- The way the codes are described, it seems that there is interlace between several models in unique code files. This can be a problem if some users are inexperienced; therefore, users of the model must have previous experience with models in order to use the combined version.
- It would be also interesting in the future to incorporate mother, fetus, lactation and infant in the same model.
- Even the 'csl' files are good, it is more tricked for the ''.m'' files. For me this part missed the objective of transparency. The 'm' files can reproduce the graph cited in the report, but it is difficult to understand the logic simulation behind them. It will be important for the upcoming user to understand the mechanics behind the result.
- If I have not missing something, it seems that the fetus model has a fixed constant (3.4 kg) for body weight. It does not consider all the fetus formation, but only the week 40. Is there a rational behind this or is it due to a lack of data?

Dale Hattis, Ph.D.

As indicated above, I disagree with the focus on the specific life stages chosen for detailed analysis. If the shift is made to quantifying cognitive impairment rather than just thyroid hormone level changes, as I recommend, I think it would be much better to model fetal and maternal perchlorate effects on perchlorate and thyroid hormone levels in early pregnancy.

There are no obvious problems with the model structures used to describe these kinetics.

Angela M. Leung, M.D., M.Sc.

Comments regarding physiology and kinetics of the model structure:

The focus of the overall model is the potential adverse effect of perchlorate exposure in the lactating mother and in the infant (both breastfed and formula-fed) during ages days 7-90 of postnatal life. The model considers the kinetics of and physiology between perchlorate exposure, dietary iodine nutrition, and serum thyroid hormone concentrations in the lactating mother, breastfed infant, and formula-fed infant. The primary endpoint is hypothroxinemia, defined as the 2.5-10^{th} percentile of serum FT4 concentrations among lactating women, breastfed infants, and formula-fed infants. Some general comments are as follows:

- It would be reasonable to consider the full HPT axis, given the interdependence of serum TSH and FT4 concentrations on the changing effects of iodine nutrition and perchlorate exposure. The assessment of serum FT4 concentrations in isolation is a limitation of the physiologic responses that occur with dynamic variations of iodine supply, as incurred with constantly changing dietary intake, breastfeeding, and urinary excretion.

- The role of coexposures by other environmental toxicants, such as thiocyanate and nitrate, should be assessed in reference to the effects of perchlorate during these life stages. The potency of perchlorate, relative to thiocyanate and nitrate, as a competitive inhibitor of iodine at NIS should be considered.
- The longterm concern of perchlorate exposure during crucial periods of early development is on the possible detrimental neurocognitive effects among exposed fetuses and infants. The current literature surrounding the associations of maternal hypothyroidism and/or hypothyroxinemia on later offspring neurodevelopment is generally better-established than that for infant hypothyroxinemia.

Regarding the applicability of the model for each of these three life stages:

a. **Lactating mother**: Perchlorate exposure in the lactating woman is assumed to be from ingestion through the diet. The present model reflects an integration of the previous PBPK perchlorate models predicting thyroidal RAIU inhibition with the PBPK iodine and BBDR thyroid hormone models, which were based on the previously published pregnancy model. For the analyses, maternal iodine intakes are assumed to range between 75-250 mcg/day, and maternal perchlorate exposures up to 20 mcg/kg/day are assessed. For reference, major points reviewed are:

- The previous *pregnancy* model (page 18, lines 1-13) assumed dietary iodine intakes of >200 mcg/day, but notes that model dose-response predictions for iodine intakes ≥150 mcg/day are judged to be similarly reliable, given the very small decrease in serum FT4 concentrations between the two levels. The pregnant mother also was predicted to have a lower baseline serum FT4 concentration (in the absence of perchlorate) than the lactating mother at postnatal day 7, given the same amount of dietary iodine.
- The *lactating* model (page 18, lines 20-25) assumes dietary iodine intakes of >250 mcg/day, but notes that model dose-response predictions for iodine intakes ≥150 mcg/day are judged to be similarly reliable, given the very small (6-14%) decrease in serum FT4 concentrations between the two models. At postnatal days 7-90, the lactating mother's serum FT4 concentrations are predicted to decrease due to the physiological changes and demands of breastfeeding.
- At postnatal day 7 for the lactating mother, the steepness of the perchlorate dose-response for maternal serum FT4 concentrations is similar to that for the pregnant mother. The model predicts that if maternal perchlorate exposure is <4 mcg/kg/day, both the pregnant and lactating mother maintain normal serum FT4 concentrations if their dietary iodine intakes are at least >150 mcg/day.
- Sensitivity analyses suggest that maternal parameters impacting breastmilk iodine concentrations, amount of breastmilk ingestion, and kinetics of thyroid hormone physiology and urinary excretion of iodine are important predictors of serum FT4 and TT4 concentrations in the breastfed infant.
- The maternal sub-model as shown in Figure 3 was reviewed in detail for this question.
    - **Strengths**:

1-- The model considers available published data regarding iodine, perchlorate, and serum FT4 physiology and concentrations during pregnancy, lactation, and early infancy, though with several important caveats.

2-- With the exception of the comments below, the maternal sub-model addresses the kinetics of iodine and thyroid hormone physiology during lactation.

- **Weaknesses**:

1-- Maternal urinary iodine levels are not accounted for in the maternal sub-model as shown in Figure 3. There are data reporting that estimated urinary iodine 24-hour excretion in the mother, rather than spot maternal urine iodine concentrations, are a good reflection of maternal iodine supply to the breastfed infant (Andersen SL et al; PMID 2419933); these data also demonstrate that breastmilk iodine concentrations are not correlated with maternal fluid intake.
2-- Also not shown in Figure 3 is the active transport and concentration of perchlorate into mammary cells during lactation by NIS (Dohan O et al; PMID 18077370), which is significant for the potential of perchlorate exposure from breastmilk to directly inhibit the infant's thyroidal iodine uptake.
3-- The relative potency of perchlorate as a competitive inhibitor of iodine uptake at NIS (30:1 affinity to iodine) should be included (Tonacchera et al; PMID 15650353).

b. **Breastfed infant**: Perchlorate exposure in the breastfed infant is assumed to be from breastmilk ingestion and focuses on the effects of exposure during postnatal days 7-90. For reference, major points reviewed are:

- At postnatal day 7, the perchlorate threshold associated with breastfed infant serum FT4 concentrations decreasing to below the lower limit of the reference range is 12 mcg/kg/day.
- During postnatal days 7-90, the model predicts that maternal perchlorate exposure reduces breastfed infants' serum FT4 concentrations, with the magnitude of decrease inversely dependent on maternal dietary iodine intake.
- During postnatal days 30-60, breastfed infants' serum FT4 concentrations would be predicted to remain within the reference range when maternal dietary iodine intakes are ≥150 mcg/day and maternal perchlorate exposure is <20 mcg/kg/day, even though maternal thyroid function is expected to be abnormal (hypothyroxinemic or hypothyroid) in these ranges.
- Overall, the model predicts a larger effect on serum FT4 concentrations in breastfed infants than formula-fed infants, due primarily to the higher perchlorate concentrations in breastmilk than infant formula in general; this discrepancy is then further exacerbated when breastmilk iodine content is low from insufficient maternal dietary iodine intake.
- The infant sub-model as shown in Figure 2 was reviewed in detail for this question.

- **Strengths:**

1-- The model considers data from the existing literature regarding iodine, perchlorate, and serum FT4 physiology and concentrations during lactation for the breastfed infant.

- **Weaknesses:**

1-- Similar to the comment above regarding the lactation mother, what is not shown in Figure 2 is the active transport and concentration of perchlorate into mammary cells during lactation (Dohan O et al; PMID 18077370), which is significant for the potential of perchlorate exposure from breastmilk to directly inhibit the infant's thyroidal iodine uptake.

2-- Perchlorate inhibition (as shown in yellow in Figure 2) might be better clarified if the potential sources of perchlorate exposure in the breastfed infant were also shown (i.e., breastmilk, formula), similar to what is shown for sources of iodine.
3-- One major limitation is the significant variability of breastmilk iodine concentrations in the existing literature upon which the model is built. Please see my comments in Question 1B regarding this.
4-- The recommendations for dietary iodine intake in infants should be referenced. The U.S. Institute of Medicine estimates that the Adequate Intake for infants ages 0-6 months is 110 mcg iodine/day. This is based on iodine turnover studies showing that iodine requirements in term infants is 15 mcg/kg/day (Comprehensive Handbook of Iodine, 2009).

c. **Formula-fed infant**: Perchlorate exposure in the formula-fed infant is assumed to be from infant formula ingestion and focuses on the effects of exposure during postnatal days 7-90. For reference, major points reviewed are:
- For all postnatal days and infant formula iodine concentrations studied (108-384 mcg/L), the model predicts infant serum FT4 concentrations to stay within the reference range.
- Perchlorate exposure from infant formula would be expected to reduce infant serum FT4 concentrations at postnatal day 7, but not between postnatal days 30-90, for all infant formula concentrations.
- The infant sub-model as shown in Figure 2 was reviewed in detail for this question.

- **Strengths:**

1-- The model considers data from the existing literature regarding iodine, perchlorate, and serum FT4 physiology and concentrations during lactation for the formula-fed infant.
2-- The infant model was developed on the assumption that the iodine content of infant formulas ranges from approximately 100-300 mcg/L. Thus, for the described kinetics of infant formula intake, these infant formula iodine concentrations are predicted to be sufficient for normal thyroid hormone production in the formula-fed infant (page 18, lines 14-17).

- **Weaknesses:**

1-- The infant sub-model as shown in Figure 2 does not show the potential of perchlorate exposure that can also occur from infant formula ingestion (Pearce EN et al; PMID 17311853).
2-- Perchlorate inhibition (as shown in yellow in Figure 2) might be better clarified if this potential source of perchlorate exposure in the formula-fed infant was also shown, similar to the what is shown for sources of iodine.
3-- The recommendations for dietary iodine intake in infants should be referenced. The U.S. Institute of Medicine estimates that the Adequate Intake (an estimation of the Recommended Daily Allowance [RDA] when there are insufficient data) for infants ages 0-6 months is 110 mcg iodine/day. This is based on iodine turnover studies showing that the iodine requirement in term infants is 15 mcg/kg/day (Comprehensive Handbook of Iodine, 2009).

Michael H. Lumpkin, Ph.D., DABT

The developed model structure adequately captures the known biological processes acting to exchange iodine, TH, and perchlorate across tissue interfaces and transport these molecules across tissue systems and out of the body. The report describes well the representation of the biology in the mathematical model structure. A possible weakness in the model is the lack of TSH expression, and the assumption that TSH expression discretely activates in a population *in*

situ at the 2.5th percentile of plasma T4/fT4. While there may not be adequate data at this time to value-populate a parameter for TSH-induced up-regulation of NIS in the thyroid or mammary gland, the addition of such a parameter followed by a local sensitivity analysis of up-downregulation of NIS would be informative to explore wither chronic perchlorate exposure and low-level TSH expression would likely or not affect plasma and breastmilk T4 levels at all life stages.

Elizabeth N. Pearce, M.D., M.Sc.

Although the choice of hypothyroxinemia as the primary outcome of interest was previously established by the SAB, the strengths and weaknesses of this approach at each life stage deserve consideration.

Strengths of this approach include efforts to identify both the particularly vulnerable life stages and the most significant public health outcomes which are potentially associated with perchlorate exposure. In thinking about the potential public health impact of perchlorate exposure, potential adverse outcomes essentially overlap those of iodine deficiency, and the potential adverse effects on fetal and child neurodevelopment are of paramount interest. There are relatively few data at present to support an effect of maternal subclinical hypothyroidism on lowered child IQ (a study by Haddow et al. included both overtly and subclinically hypothyroid women: Haddow JE, Palomaki GE, Allan WC, Williams JR, Knight GJ, Gagnon J, O'Heir CE, Mitchell ML, Hermos RJ, Waisbren SE, Faix JD, Klein RZ 1999 Maternal thyroid deficiency during pregnancy and subsequent neuropsychological development of the child. N Engl J Med 341:549–555). However, there is a growing body of evidence demonstrating adverse child developmental effects of maternal hypothyroxinemia in pregnancy (in addition to those cited in the report, see papers listed below under 3A). Importantly, these studies have assessed maternal free T4 in early to mid-gestation; links with third-trimester maternal hypothyroxinemia have not been established.

There are some limitations regarding the choice of hypothyroxinemia at certain life stages as the primary outcome of interest. Despite the observational data suggesting a link between early gestational maternal hypothyroxinemia and adverse child developmental outcomes, there are now two randomized clinical trials (Lazarus JH, Bestwick JP, Channon S, Paradice R, Maina A, Rees R, Chiusano E, John R, Guaraldo V, George LM, Perona M, Dall'Amico D, Parkes AB, Joomun M, Wald NJ 2012 Antenatal thyroid screening and childhood cognitive function. N Engl J Med 366(6):493-501 and [HYPERLINK "http://www.ajog.org/article/S0002-9378(15)01319-8/pdf"]) which demonstrate no benefit of levothyroxine treatment for maternal hypothyroxinemia on child IQ. (It is worth noting that both of these trials were limited by relatively late initiation of therapy; at 13 weeks in CATS and at 17 weeks gestation in the Casey study.) Given both the lack of interventional data demonstrating treatment benefit, and the challenges of establishing maternal free T4 reference ranges and treatment targets, current clinical guidelines (including in-press updated guidelines from the American Thyroid Association) largely recommend against levothyroxine treatment for isolated maternal hypothyroxinemia. In addition, in lactation, maternal hypothyroxinemia has not been defined as a clinical syndrome and has not been linked to any adverse outcomes. Therefore, normative reference ranges for thyroid function tests specifically in lactation have not been established.

Infant hypothyroxinemia might lead to impaired neurodevelopment, but data for normal free T4 ranges in infants are limited.

The lack of consideration of the HPT axis in the BBDR model is a very substantial limitation of the model at each life stage. Clinically it is virtually never appropriate to interpret free T4 in isolation, without consideration of the serum TSH and other thyroid function test values. Decreases in thyroid hormone stimulate increases in TSH; higher TSH levels, in turn, will increase the affinity of the thyroid for iodine uptake, increase the ratio of T3 to T4 synthesized by the thyroid (which may have important implications for the fetus, given that transplacental passage of maternal thyroid hormone is primarily of T4, not T3), and cause thyroid hyperplasia. There is also a good deal of interpersonal variation in compensatory mechanisms, so that I am not sure it is fair to state (as on page 69) that hypothyroidism is expected when the free T4 drops to the 2.5th percentile.

It is notable that environmental exposures to perchlorate do not occur in isolation; exposure to thiocyanate and nitrate is equally ubiquitous and works by the same mechanism of NIS inhibition. It, therefore, would seem pertinent to include variable co-exposure to thiocyanate and nitrate in the models. Given available data in the literature about exposures at different life stages and about the relative effects on NIS inhibition, this addition would likely not be terribly difficult.

Excessive, as well as inadequate iodine exposure is associated with adverse effects on thyroid function; models do not appear to account for potential non-linear effects of iodine exposure on thyroid hormone status. This is likely not of concern at the range of iodine intakes being studied, but this could at least be considered.

Stephen M. Roberts, Ph.D.

When the SAB Perchlorate Advisory Panel recommended a novel approach for perchlorate MCLG development, it envisioned a framework with which the complexities of a perchlorate MOA could be addressed using a PB/PK-PD approach, extending from perchlorate exposure through NIS inhibition to thyroid hormone changes and finally to neurodevelopmental impacts. While some useful modeling had already been done, it was recognized that building out all of the PK and PD aspects could take considerable time and resources, as well as new research. In view of practicalities, including the need to develop a new perchlorate MCLG in a timely manner, some interim steps were suggested that could lead to a scientifically defensible MCLG that could be updated as the model is refined in the future. A strength of the BBDR model structure proposed here is that it includes all of the essential elements: perchlorate and iodine PK, NIS inhibition, and thyroid hormone changes associated with neurodevelopmental effects. It addresses all of the sensitive life stages identified by the SAB panel.

There are pieces that are missing — limitations may be a better term than weaknesses. One is the influence of co-exposure to other goitrogens and another is the inclusion of more explicit quantitative relationships between thyroid hormone disturbances and neurodevelopmental outcomes. Both were noted by the SAB panel as desirable to include, but were considered to be elements that could only be added in a meaningful way after additional research.

Given the information that is available now with which to construct a PB/PK-PD (BBDR) model, I have no problems with the overall model structure presented, and accept the explanations for simplification of some of aspects of the model from previous versions (i.e., reduction in thyroid subcompartments and direct transfer of iodide from mammary plasma to milk). Within the constraints of the model, its ability to "adequately and accurately describe the physiology and kinetics of iodine, thyroid hormones, and perchlorate during different life stages" is a function largely of the values chosen for the various parameters rather than the model structure itself.

Joanne F. Rovet, Ph.D.

As above, the model appears to be stronger regarding kinetics of iodide and effects of perchlorate on iodide synthesis than in specifying thyroid-hormone actions and making predictions from the latter set of specifications. The HP-part of the HPT axis is not included nor is the role of deoidinases. The assumption that fT4 is converted equally to fT3 and RT3 is in my belief not correct, even though accepted in the Lumen et al (2013) model. It is well established that within the brain, T4 is the primary hormone of action. T4 enters the brain via the glia, where it is locally to T3 by the D2 enzyme. These pathways are not currently considered. Additionally, free T4 is considered the key hormone but isn't bound hormone (as measured by total T4) the hormone that gains entry into the brain at the blood-brain barrier or choroid plexus? Finally, the assumption that the P7 infant is equivalent to the neonate is wrong given Vulsma's data showing a steep drop-off in levels of T4 following birth in children with congenital hypothyroidism, thought to reflect the loss of the maternal contribution following parturition. To my knowledge, no evidence exists showing the infant thyroid gains this capacity in the first week of life.

The breast-feeding infant model combined with the lactating mother is to me a single system that is well thought out in showing points of impact of perchlorate, whereas the bottle-feeding infant model fails to realize the impact of perchlorate in the water used to prepare formulas after the infant has graduated from premade formulas (at about 1 month of age). A greater risk of hypothyroxinemia in the lactating than bottle-feeding mother is not known and it is not clear to me why this would represent a sensitive stage when the real issue is the developing brain and its high need for thyroid hormone. Perhaps authors were considering the relationship between hypothyroxinemia and maternal depression in the post-partum period. However, to my knowledge, the only person to study this is Victor Pop who examined prenatal, not postnatal, hypothyroxinemia and this would be equally present in both types of mothers (i.e., those who do and those who do not breast feed).

Question 1B. Are the physiological and kinetic parameters for iodine, thyroid hormones, and perchlorate for these life stages supported by the published sources for those parameters or data used to identify parameters via calibration? Please identify any critical data gaps and suggest additional data or parameter (values) to these proposed model parameters to address identified gaps.

Hugh A. Barton, Ph.D.

The basis for the model parameters is provided in Tables 4 – 8. In general, it appears the parameters are supported by some information (sometimes visually fitted to the data or the data used directly as table functions).

As also noted in public comments, when the basis of a parameter value is provided as a previous modeling effort (e.g., Fisher et al 2016, Lumen et al 2013), this is a secondary source that does not directly identify the supporting information. In several cases additional information is provided, for example the original data source used for the previous modeling. Ideally, this approach would be used for all instances where other models are noted.

In addition, as also noted in public comments, the report states on p 23 that "The review process was halted after it was judged that the objective had been met; i.e., sufficient data for model calibration had been identified." It is not clear what the statement means or how it was decided there were sufficient data. It is also not clear if this means the review of papers from the Dec 2013 search was halted or that further searches of literature were halted. Finally, given the time required to develop the model and prepare documentation, context should be provided for the Dec 2013 date, e.g., initiation of this model development effort, so it does not appear to be several years out of date for no reason. While it will likely never be possible for the model to catch up with the most current publications, it might be reasonable to carry out searches to determine what new publications were available and whether they essentially augmented existing information (e.g., another cohort of pregnant women with similar measures as previously existed) or potentially provide new information about parameters with assumed values.

Claude Emond, Ph.D.

The physiological parameters are clearly and transparently presented in both model CSL files. When no data were present in the literature to establish the biological relevant, the authors optimized the parameters to fit the biomonitoring human data published. The review draft is very well referenced and helps to build our confidence in using the model.

Dale Hattis, Ph.D.

Briefly, I find several of the comparisons between observations and model predictions unconvincing. For urinary iodide the key discussion appears on page 60:

*"First, model predictions of urinary iodide concentrations for the formula-fed infant were compared with data from Gordon et al. (2014) and Cao et al. (2010). The model simulations were performed based on formula concentrations of iodine reported by Pearce et al. (2004) and perchlorate by Schier et al. (2010). Urinary iodide predictions were not sensitive to perchlorate exposure levels, so for these simulations, the geometric mean perchlorate concentration (0.92 14 µg/L) of all formulas analyzed by Schier et al. (2010) was used for the iodide comparisons (**Figure 4**, top panel). The model-predicted urinary iodide concentration for formula-fed infants with iodine concentrations at the lowest reported value of 108 µg/L by Pearce et al. (2004) were within the range of literature-reported values (**Figure 4**) from Gordon et al. (2014) and from Cao et al. (2010) for both cow milk-based and soy-based formula."*

The figure referred to has an enormous amount of scatter, even with the data points plotted on a logarithmic y-axis. To then say, given this scatter, that "the model-predicted urinary iodide concentrations…were within the range of literature-reported values (Figure 4) really is such a loose standard that it seems hardly meaningful. Minimally there needs to be some statistical summarization of the comparison data and some specific comparison of the summary data with specific sets of model predictions from models incorporating a range of possible values of key parameters.

The perchlorate comparison is discussed on page 61:

*For perchlorate, data for urinary concentrations were only available for formula-fed infants from Cao et al. (2010). To cover the range of literature-reported perchlorate concentrations, simulations are shown for 0.18 µg/L (minimum measured by Schier et al. (2010)), 0.92 µg/L (geometric mean of values for both soy and cow milk formulas from Schier et al. (2010)), and 4.1 µg/L (maximum value from Pearce et al. (2004), which is higher than the maximum measured by Schier et al. (2010)). Model-predicted concentrations of perchlorate were within the reported values for cow and soy formulas (**Figure 4**, bottom panel)*

The comparison depicted in the bottom panel is also unconvincing, lacking any statistical summarization to help the reader judge whether the comparison supports or refutes the predictions of the model.

Further discussion of the comparison of perchlorate levels appears on page 63:

*The model-predicted urinary perchlorate concentrations were within the range of reported values for birth to 90 days for both formula-fed and breast-fed infants, when perchlorate daily intake was assumed to vary between 0.001 and 1 µg/kg/d (**Figure 6**; data from Leung et al. (2012) and Cao et al. (2010)). Since iodine intake between 75 and 250 µg/day had no effect on predicted urinary perchlorate levels, the iodine intake by the lactating mother was assumed to be 150 µg/day for the perchlorate comparison: a low level within the plausible range for which the model is assumed valid. Since iodine intake has very little effect on predicted perchlorate kinetics, the exact choice of iodine level is not important for this comparison.*

Similarly the conclusion from Figure 6 that the predicted perchlorate concentrations are "within the range of reported values" is completely unconvincing. What is shown in Figure 6 is a plot of

highly scattered observations plotted over a four order of magnitude range with no statistical summarization of the data to allow reasonable juxtaposition of the central tendency and uncertainty range of the observations with corresponding model expectations.

There is a discussion of a comparison of iodide levels on page 64:

*Note: it has been suggested that iodide levels are not stable in breast-milk samples (Dr. Benjamin Blount, CDC, personal communication), which may explain in part why many of the data in **Figure 7** (also see **Figure 17**) are well below the model simulations for 150 and 250 µg/d maternal iodine intake. The predictions for the lowest iodine intake of 75 ug/d are closer to the middle of the range of the data.*

The lack of correspondence of the data points to model predictions is unsettling. And the proffered explanation "that iodide levels are not stable in breast-milk samples" is no help. Instability would be expected to lead to scatter of the data points, but not a systematic bias lowering the data points relative to model expectations. The modelers' response in this case makes no sense.

The overall conclusion of the authors appears on page 67:

*Overall, the model predictions were considered adequate based on the comparison of model 11 simulations to data in **Figure 4-Figure 9***

I disagree. The authors should develop a range of alternative models that would fit these data as well or better based on much more rigorous criteria than that the models produce results "within the range" of the observations presented on multi-order-of magnitude plots. They should then consider and document range of policy-relevant parameter values indicated by running the alternative models with the range of plausible calibrations.

Angela M. Leung, M.D., M.Sc.

Comments regarding calibration parameters:

The models consider published literature to support the calibration parameters for iodine, thyroid hormones, and perchlorate in the lactating mother, breastfed infant, and formula-fed infant.

a. **Lactating mother calibration parameters:**
   - **Iodine in the lactating mother**:
     - Variability of breastmilk iodine concentrations: The parameters for breastmilk iodine concentrations are based on mean values drawn from women examined in relatively small studies. One potentially substantial limitation is that data demonstrating a significant variation of breastmilk iodine concentrations following the ingestion of dietary iodine (Leung et al; PMID 23050787) was not included in the model. In this study of 16 healthy euthyroid lactating women, dietary iodine consumption (600 mcg oral KI) following an overnight fast increased breastmilk iodine

concentrations by nearly 8-fold within a few hours, thus illustrating the limitations in the interpretation of random breastmilk iodine content measurements and the challenges of basing the model on mean breastmilk iodine values from relatively small studies. This is hinted at on page 40 lines 5-10 and also on page 6/Figure 6. From the data of Leung et al. (PMID 23050787), the statement on page 40 lines 8-10 is thus inaccurate. Given the impossibility of ascertaining the influence of recent dietary iodine intake in relation to breastmilk iodine values reported in the literature, one can perhaps assume that the lowest and highest range of reported breastmilk iodine values may be that representing all scenarios of dietary iodine intake; this is important to note in the model report as a limitation and caveat to the model. Incidentally, the median (IQR) *fasting* breastmilk iodine concentration in this study was 45.5 mcg/L (34.5-169 mcg/L), which is comparable to the Leung 2012 study used for calibration of the current model.

- Mean breastmilk iodine concentrations: Recognizing that in the absence of a larger study assessing the impact of dietary iodine on breastmilk iodine concentrations, the model can only rely on mean breastmilk iodine concentrations taken from random collections as much as possible. Other U.S. data on breastmilk iodine concentrations have been reported in 57 healthy women (Pearce et al; PMID 17311853) that are not included and can be used to improve the calibration of the model. This study by Pearce et al also reports the perchlorate content in the subjects' breastmilk; urinary iodine and perchlorate concentrations; and 17 brands of infant formula that subjects reported use of during pregnancy.
- Breastfeeding exclusivity: An important caveat is that many of the studies in the literature did not examine women who were exclusively breastfeeding, and thus the iodine nutrition provided to their infants was derived from a combination of breastmilk and formula sources. Calibration of the model to the published ranges of iodine and concentrations in breastmilk, maternal urine, and infant urine, and for infant serum thyroid hormones may thus be inaccurate.

- **Thyroid hormones in the lactating mother:**
  - TT4 reference range:

1. The *pregnancy* model is based on TT4 reference ranges as reported in 6 studies (page 20, lines 5-7). The *lactation* model is based on serum FT4 concentrations from only 48 total women from two NHANES cohorts (page 20, lines 16-22). The small n used for the lactation model is concerning for its accuracy. Also, it should be stated clearly in the text that the following influence serum thyroid hormone concentrations during pregnancy and lactation: preexisting thyroid disease and/or use of thyroid hormone replacement or antithyroidal medications, positive serum thyroid autoantibodies, hyperemesis gravidarum, trophoblastic disease, and preeclampsia, and whether these were assessed in any of the quoted studies from which the models are based.

2. There are several potential concerns regarding the adaptation of the human pregnancy thyroid physiology model for use in the lactation model. In general, thyroid hormone requirements are increased in pregnancy, compared to lactation, due to the following factors: 1) It is well-known that thyroid hormone requirements and thus, thyroid hormone production, increases by approximately 2-fold from the beginning of pregnancy to mid-gestation, due primarily to the increases in thyroid binding globulin (TBG) that is seen with increased estrogen levels during pregnancy (Glinoer; PMID 9183570). The thyroid hormone requirements decrease back to pre-pregnancy levels following delivery. 2) There are rises in serum FT4 concentrations, particularly during the first trimester, due to the rise of beta-HCG during this timeframe. 3) There is an increase in plasma volume during pregnancy that corresponds to increased thyroid hormone requirements during pregnancy. 4) There is an acceleration of serum T3 and T4 degradation during pregnancy, due to the effect of abundant type 3 deiodinase expression and activity in the placenta and uterine and fetal tissues. In summary, for these reasons, the extrapolation of serum thyroid hormone levels during pregnancy for use in lactation is not ideal (page 14 lines 11-12). For the lactation model, non-pregnant serum thyroid hormone concentrations would be more accurate.

- **Perchlorate in the lactating mother:**
  - The report states that the details of the EPA perchlorate and radioiodide PBPK models for the lactating mother are referenced in McLanahan et al 2014 and U.S. EPA 2009. The current model was simplified from the previous PBPK models according to the following changes: the thyroidal subcompartments for perchlorate was reduced to plasma and tissue (similar to iodine), and perchlorate transport in mammary cells is shown to occur as a one-step process from plasma to breastmilk. Key perchlorate PBPK model parameter changes resulting from these revisions are summarized on pages 44-45 of the report. My expertise is not in this area, and I am unable to comment further regarding this question.

b. <u>Breastfed infant calibration parameters</u>:

- **Iodine, thyroid hormones, and perchlorate in the breastfed infant**:
  - <u>Leung et al 2012 publication</u>: It should be noted that the report by Leung et al 2012 used in calibration of the model included both exclusively breastfed infants (35% of the sample size), as well as those who also partially consumed infant formula (65% of the sample size). This clarification is missing from Table 2 and in the corresponding text; it is a significant limitation of the current model, as it assumes that all data was obtained from exclusively breastfed infants.
  - <u>Cao et al 2010 publication</u>: Similarly, this report included both breastfed infants (46% of the sample size) and formula-fed infants (54% of the sample size), as noted in Table 2. The use of urinary iodine and perchlorate concentrations from this study for model calibration thus is not completely accurate when assuming they are resulting from exclusive breastfeeding or exclusive formula-feeding.

- Colostrum iodine concentrations: The report outlines the reasons for not analyzing neonates between days 0-7 of postnatal life, primarily the physiologic surge of TSH levels in the immediate postpartum period, which is a valid argument. However, there are data examining perchlorate and iodine levels in colostrum (form of breastmilk beginning in late pregnancy and continuing in the first few days after delivery) and in the urine of postpartum women (Leung et al; PMID: 18616704). These data may be helpful to include in the report to further strengthen the current model's relationships between perchlorate exposure and breastmilk iodine levels in lactating women; the relationship does not have to be included in the model, but can be used to assess trends of the impact of perchlorate exposure when comparing neonates <7 days to those >7 days of newborn life. A study has reported that the estimated iodine intake from breastmilk and infant formula during this early period, days 1-2 after birth, are 20.0 ± 11.9 mcg/day and 13.0 ± 3.3 mcg/day, respectively (Gokmen IG et al; PMID 7661341).
- Maternal 24-hour urinary iodine excretion: There are data reporting that estimated urinary iodine 24-hour excretion rates in the mother are a better reflection of iodine supply than perhaps breastmilk iodine to the breastfed infant (Andersen SL et al; PMID 2419933) for the reasons delineated in response #1Ba (*calibration parameters for breastmilk iodine in the lactating mother*). It is interesting to note that these data by Andersen et al also demonstrate that breastmilk iodine concentrations are not correlated with maternal fluid intake.

c. **Formula-fed infant calibration parameters:**

- **Iodine in the formula-fed infant**: The model is built on data by Pearce et al 2004 that reported the iodine content of eight brands of U.S. infant formula. Given this limited data, it may be worthwhile to also consider additional available data:
  - There is an additional study of U.S. brands of infant formula reporting a detectable range of perchlorate in all 17 products tested (range, 0.22-4.1 mcg/L) (Pearce EN et al; PMID 17311853).
    - Although it is a Spanish study, the measured iodine content of 27 brands of infant formula in Spain (Fernandez-Sanchez LM et al; PMID 18039487) report a mean iodine concentration of 53.5 ± 19.5 mcg per 100g sample.
    - Additional data regarding the iodine content of infant formulae are also described in the Comprehensive Handbook of Iodine 2009, which should be considered and referenced.
- **Urinary iodine, urinary perchlorate, and serum thyroid hormones in the formula-fed infant:**
    - Leung et al 2012 publication: It should be noted that the report by Leung et al 2012 used in calibration of the model included both exclusively breastfed infants (35% of the sample size), as well as those who also partially consumed infant formula (65% of the sample size). This clarification is missing from Table 2 and in the corresponding text; it is a

significant limitation of the current model, as it assumes that all data was obtained from exclusively breastfed infants.

- Cao et al 2010 publication: Similarly, this report included both breastfed infants (46% of the sample size) and formula-fed infants (54% of the sample size), as noted in Table 2. The use of urinary iodine and perchlorate concentrations from this study for model calibration thus is not completely accurate when assuming they are resulting from exclusive breastfeeding or exclusive formula-feeding.

Michael H. Lumpkin, Ph.D., DABT

The report describes in detail the selection of data that serve as the basis of model parameter values for the various life stages. This includes the consideration of data published or made available since publication of the respective Lumen/Fisher/Clewell/McClannahan models. I am not aware of additional data that should be considered or preferentially utilized in the place of data described in the report.

Elizabeth N. Pearce, M.D., M.Sc.

Free T4 assays, as noted in the text, are poorly concordant with each other in pregnancy and some assays lose the expected inverse relationship with serum TSH values (Lee RH, Spencer CA, Mestman JH, Miller EA, Petrovic I, Braverman LE, Goodwin TM. Free T4 immunoassays are flawed during pregnancy. Am J Obstet Gynecol. 2009;200(3):260.e1-6.). It is generally recommended that normal thyroid function reference ranges be assay-specific, and that they should be defined in populations of individuals with no known history of thyroid disease, with adequate iodine intakes, and with negative thyroperoxidase (TPO antibodies). Among the studies used to derive free T4 reference values for the pregnancy BBDR models, the studies by Yan, Sticker et al. clearly met those criteria. The paper by Gong and Hoffman excluded TPO positive women; the sample was from Toronto, which likely means it was iodine sufficient. Similarly, the study by Wang et al. did not specify the study population's iodine status, although women were TPO Ab negative. In the study by Khalid et al., TPO antibody positivity was excluded and although urinary iodine was not ascertained, the study population, from Ireland, was most likely mildly to moderately iodine deficient. Additional data which could inform the definition of normal free T4 values in pregnancy are listed below under section 3A.

Hypothyroxinemia in lactating women, as noted above, is not currently considered a clinical adverse outcome, and thus there is essentially no literature on this entity. After the first 2-3 weeks postpartum (when levels are equilibrating after the changes of pregnancy), there is no reason to believe that reference intervals for free T4 should be any different in lactating women than they are for non-pregnant, non-lactating women. Unlike in pregnancy, there is not a strong hormonal driver for increased thyroid hormone production or metabolism. The amount of thyroid hormone secreted in breast milk is negligible (van Wassenaer AG, Stulp MR, Valianpour F, Tamminga P, Ris Stalpers C, de Randamie JS, van Beusekom C, de Vijlder JJ 2002 The quantity of thyroid hormone in human milk is too low to influence plasma thyroid hormone levels in the very preterm infant. Clin Endocrinol (Oxf) 56(5):621-627). Therefore, it should be possible to use the broader dataset for TPO negative, age-matched, non-pregnant

women from NHANES as well as data from other published sources to inform reference ranges for free T4 in the women who are lactating. The model currently uses data from only 39 lactating women from NHANES 2007-2008 and 2009-2010; this data set is very small and may include women with thyroid autoimmunity. Excluding TPO antibody positive women in the validation datasets for lactating women is particularly important because up to 10% of women experience postpartum thyroiditis, which will alter thyroid function values.

Decreasing excretion of urinary iodine in seven women over time was noted by Aboul-Khair et al. in data used to inform urinary iodine values for lactating women in the BBDR model. I am not able to access this paper, but have concerns about both the very small sample size and about what was known about the underlying iodine sufficiency of the women studied. Trends over the course of the first 90 days postpartum might be quite variable depending on ongoing iodine intake and presence or absence of adequate intrathyroidal iodine stores.

Table 6: The fractional kidney blood flow in third trimester women is assumed to be the same as for lactation. However, glomerular filtration rates and renal plasma flow are thought to be substantially increased in pregnancy (Dunlop W. Serial changes in renal hemodynamics during normal human pregnancy. Br J Obstet Gynaecol. 1981;88(1):1–9.).

Table 8: The free fraction of total T4 was estimated at 9×10^{-5} whereas it is estimated as 1×10^{-4} in lactating women. These fractions do not appear to fit with the knowledge that thyroxine binding globulin concentrations are increased twofold in pregnancy (Ain KB, Mori Y, Refetoff S. Reduced clearance rate of thyroxine-binding globulin (TBG) with increased sialylation: a mechanism for estrogen-induced elevation of serum TBG concentration. J Clin Endocrinol Metab. 1987;65(4):689.).

Page 43: it is noted with respect to the model for lactating women that "the clearance rate for metabolism or deiodination of T4 was set equal to the value for pregnant women.": This is likely inappropriate; given the high levels of type 3 deiodinase found in the placenta, the rate of thyroid hormone metabolism would be expected to be higher in pregnancy than in lactation. Page App-12: It its stated that "while there was uncertainty regarding the urinary clearance of perchlorate in lactating women vs. non-lactating women, there were no data or known biological reasons to expect it to be significantly different": this assumption is reasonable. However, on page App-17 it is noted that "maternal clearance of perchlorate is assumed to be lower during pregnancy": it seems more likely that the opposite would be true, given increased glomerular filtration rates in pregnant women.

Stephen M. Roberts, Ph.D.

Citations are provided for physiological and kinetic parameters taken from published sources. There are numerous data gaps for physiological and kinetic parameters, and these are discussed in the section on BBDR Model Development and Parameterization (beginning on page 22) in the context of the rationale for selection of various specific values. I have no substitute values to suggest.

Joanne F. Rovet, Ph.D.

The SAB-PAP report stressed the need to look at pregnancy and fetal thyroid function as key sensitive stages. Current authors maintain they did not include these stages as the relevant data for modelling are not available. This is surprising as much data exist on maternal thyroid levels and fetal data are available in the work of Thorpe-Beeston and on preterm infants (e.g., see work of Hume and Williams). Data too from the Rotterdam, Chinese, and Scandinavian cohorts could likely fill in a number of gaps. Authors need to see the paper by Peter Taylor et al (2014) on perchlorate in pregnancy and offspring IQ. Authors do extrapolate results to pregnant women and fetus, but I am not sure how this is done and when in pregnancy or fetal development this represents.

Question 1C. While the model predicts the dose-response for fetal thyroid hormones, a reference range for the fetus was not identified. Are there additional data, parameters, or (sub)models available that might be useful for evaluating fetal effects? If not, can the predictions for thyroid hormone changes in the pregnant mother be used as a measure of potential fetal effects?

Hugh A. Barton, Ph.D.

This reviewer cannot comment on this question.

Claude Emond, Ph.D.

This limitation regarding the reference range for the fetus might be an issue. It is discussed in the current draft review. As far as I know, there is not another reference that the authors might have forgotten to include in the PBPK model that suggests the possibility to describe the interaction of the fetus with the T3 and T4 hormones during gestation. This might be an issue; therefore, I believe that the reference range for the fetus should be part of the recommendation to generate data. T3 and T4 are highly important hormones in general development, including the brain. A lower concentration of fT4 and T4 resulting from perchlorate disruption would be an important issue to resolve.

Dale Hattis, Ph.D.

The emphasis on a "reference range" for hormone levels is, I think, a mistake. The implication is that values within the reference range carry no risk of harm and concern for adverse effects only arises if an individual who would ordinarily be in the reference range is moved by an exposure outside of the range. In fact, the most recently published analysis of data from a large prospective study[6] suggests that there is an optimum level of maternal free thyroxine for neurodevelopment, and a continuous form for changes in later IQ with both upward and downward departures from this optimum:

[6] Op. cit, ref. 1 above.

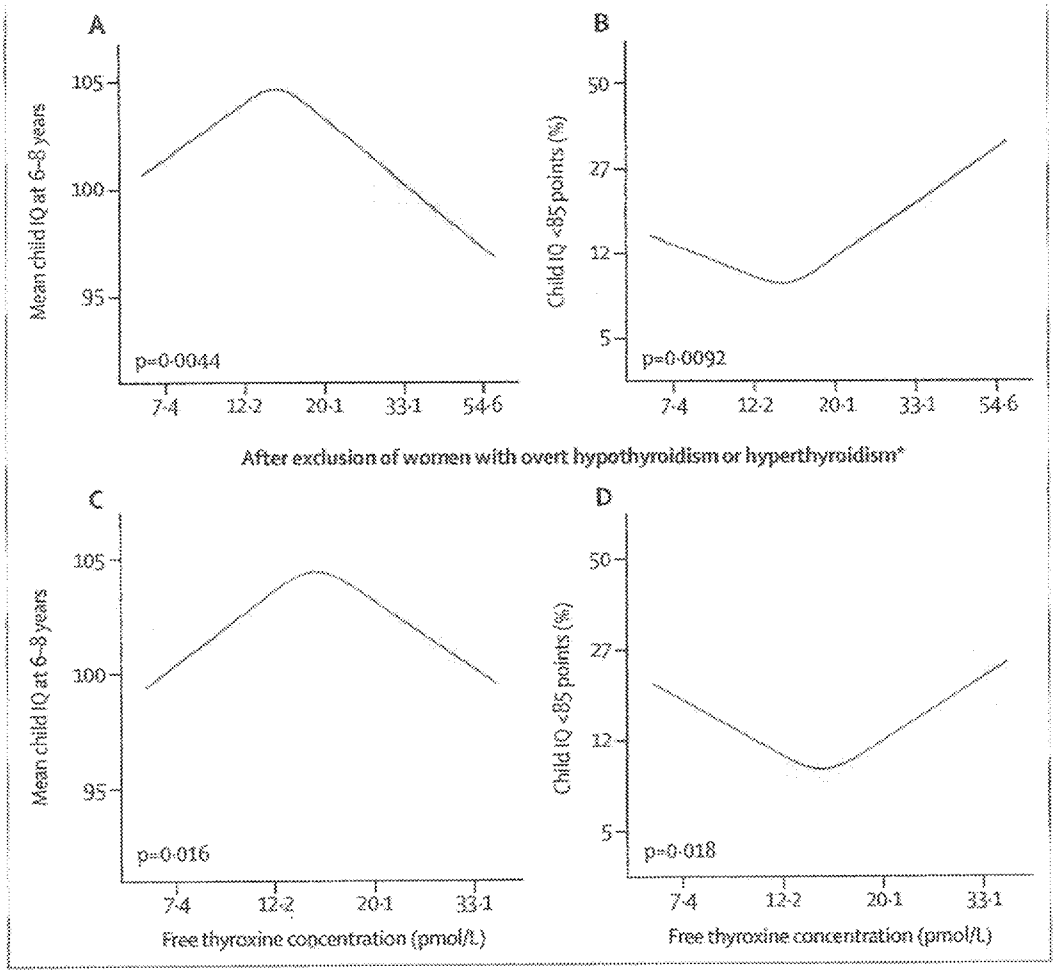

***Figure 2:* Association between maternal free thyroxine and offspring IQ**
(A, C) Association between maternal free thyroxine concentrations during pregnancy and child IQ as predicted mean and 95% CI in the whole population (A) and after the exclusion of women with overt thyroid disease (C). (B, D) Association of maternal free thyroxine levels during pregnancy and the risk of child IQ below 85 as predicted back-transformed log odds with 95% CI in the whole population (B) and after the exclusion of women with overt thyroid disease (D). Scales for the x-axis might differ between the upper and lower graphs because of exclusions of women with overt, but not subclinical, disease entities. Appendix p 5 provides effect estimates from standard linear regression models. IQ=intelligence quotient. *Overt hypothyroidism and hyperthyroidism are defined as the biochemical diagnosis made during pregnancy, based on the central 95% reference range, as advocated in international guidelines.

Source: Korevaar et al., ref. 1 above.

It must be noted that these plots have logarithmic axes for the independent variable, free thyroxine concentration. This means that if the relationships were plotted on linear axes, the lines to the left of the optima would appear much steeper than the lines to the right of the optima. The net effects need to take into account both the baseline population distribution and the net changes expected both to the left and the right of the optima.

Angela M. Leung, M.D., M.Sc.

Comments regarding fetal thyroid hormone concentrations:

The model's primary outcome is hypothyroxinemia as mediated by iodine status. However, hypothyroxinemia in the fetus was not able to be estimated by the current model, due to the inavailability of "in utero" fetal FT4 reference ranges in the current literature.

The fetus is one of the population subgroups who may be particularly susceptible to perchlorate exposure, given its biologic action on thyroidal iodine availability and therefore thyroid hormone production and brain development. Brain development in utero begins as early as 5 gestational weeks (Berbel et al; PMID 17962037). As the fetal thyroid gland is not functional until approximately 18-20 gestational weeks (Smallridge RC et al; PMID 11397821), normal brain dependent in the fetus is completely reliant on maternal transplacental passage of adequate thyroid hormone. However, even at 5 gestational weeks, the fetal thyroid is immature and thus continues to depend on maternal thyroid hormone throughout the rest of gestation, such that up to 50% of fetal T4 at delivery is that which is derived from the mother. As such, predictions of maternal thyroid hormone changes during pregnancy can serve as only a partial measure of thyroid hormone status in the fetus.

Michael H. Lumpkin, Ph.D., DABT

I am not aware of additional data, parameters, or submodels available that might be useful for evaluating fetal effects independent of the maternal effects. Historically, the use of maternal internal dosimetry and pharmacodynamics have been accepted as adequate surrogates for fetal internal doses or effects, are preferable to using maternal administered dose for extrapolation to fetal effects.

Elizabeth N. Pearce, M.D., M.Sc.

Fetal thyroid function cannot be directly measured without risk to the pregnancy. Therefore, there are no human studies examining fetal thyroid function. I think it is entirely reasonable to use maternal thyroid function as a proxy, especially given the data for adverse child developmental effects in association with early gestation maternal hypothyroxinemia. As noted above, however, I think it is important to extend the BBDR model to cover the first and second trimesters of pregnancy because there are currently no data for associations between third-trimester maternal hypothyroxinemia and adverse developmental outcomes.

It is also worth noting the recent study by Taylor et al (Taylor PN, Okosieme OE, Murphy R, Hales C, Chiusano E, Maina A, Joomun M, Bestwick JP, Smyth P, Paradice R, Channon S, Braverman LE, Dayan CM, Lazarus JH, Pearce EN. Maternal perchlorate levels in women with borderline thyroid function during pregnancy and the cognitive development of their offspring: data from the Controlled Antenatal Thyroid Study. J Clin Endocrinol Metab. 2014;99(11):4291-8.) in which we found that in an iodine-deficient cohort maternal urinary perchlorate levels in the highest 10% increased the odds of offspring IQ at age 3 being in the lowest 10%, with a greater adverse impact observed for verbal IQ than for performance IQ. Maternal levothyroxine

therapy did not appear to reduce the negative impact of perchlorate on offspring IQ. These data require confirmation in larger cohorts, and are perplexing because previously no association between maternal thyroid function and maternal urinary perchlorate concentrations were observed in this cohort (Pearce EN, Lazarus JH, Smyth PP, He X, Dall'amico D, Parkes AB, Burns R, Smith DF, Maina A, Bestwick JP, Jooman M, Leung AM, Braverman LE. Perchlorate and thiocyanate exposure and thyroid function in first-trimester pregnant women. J Clin Endocrinol Metab. 2010;95(7):3207-15).

Stephen M. Roberts, Ph.D.

Concern for the fetus as a sensitive life stage with respect to perchlorate effects is based in large part on observations of neurodevelopmental deficits among offspring of women who were thyroid deficient during pregnancy. The SAB Perchlorate Advisory Panel recommended that the EPA consider as a sensitive population the fetuses of hypothyroxinemic pregnant women; hence the need to develop a model capable of predicting the potential influence of perchlorate on hypothyroxinemia in pregnant women. Prediction of perchlorate effects on fetal thyroid hormones is not required in order to derive a perchlorate limit protective of neurodevelopmental effects from exposure during gestation. In fact, with the current state of knowledge, both attempts to estimate fetal thyroid changes and to quantify neurodevelopmental effects as a result of those changes would be highly uncertain.

Joanne F. Rovet, Ph.D.

See above. As a writer of the SAB-PAP report, I find this lack of data very disappointing. Yes, thyroid hormone changes in the pregnant mother can be used as a measure of potential fetal effects, especially in early pregnancy when the mother is the sole source of thyroid hormone for the fetal brain – and mothers' levels are known. Also, data from studies of preterm infants by the Scottish group under Hume and Williams can indicate thyroid-hormone capacity of the fetus in the third trimester.

Question 2. Modifications to existing models: EPA has modified one parameter in the 2013 Lumen et al. model: KM_TPNG, the Michaelis-Menten constant for the sodium-iodide symporter for perchlorate based on Schlosser (2016), and a second key parameter in the 2009 USEPA/2007 Clewell et al. PBPK models: VMAXC_MKP, the maximal velocity for perchlorate transfer to breast milk from those components in the USEPA 2009 models. These two parameters affect perchlorate transport from the mammary plasma to breast milk (VMAXC_MKP) and the strength with which perchlorate inhibits iodine transport by the sodium-iodine symporter (KM_TPNG). Detailed information on the assumptions and data considered in making these changes are provided in the report appendices. Are the changes scientifically supported and reasonably estimated?

Hugh A. Barton, Ph.D.

The change in Km value published in Schlosser (2016) is a reasonable scientifically supported reanalysis of the data used to establish that value. The logic presented of how the previous analysis had obtained the original Km value and the approach looking across the range of the available data is appropriate. Assuming this value to be life stage independent is an assumption, but a reasonable one absent other information.

It is more challenging to evaluate the change in VMAXC_MKP as the data are fairly scattered and addressing the range of perchlorate in milk versus urinary excretion required adjustments to other parameters, QMWB, mammary blood flow and PAMKC-P, passive diffusion of perchlorate. The approach appears reasonable, though absent working with the model directly it is difficult to have a clear perspective.

Claude Emond, Ph.D.

Lines 2 through 8, page 45

- The affinity constant (Km) for binding of perchlorate to the sodium-iodide symporter (NIS) (KM_TPNG) was reduced from 1.6×10^5 ng/L to 6×10^4 ng/L (Schlosser, 2016) because the in vitro data were reanalyzed (Kosugi et al., 1996). The same report suggests that making this modification results in a better prediction of the radioiodine uptake inhibition data from Greer et al. (2002) for the dose of 100 µg/kg/d than the simulation observed with the previous Km.

Lines 17 through 23, page 45

- Vmax for perchlorate transport from the mammary plasma to the milk call (VMAXC_MKP) also had a significant impact on model predictions. The authors were precise because they increased this value from the original model by a factor of 2.24; however, in the code file, they referred to this change because of ''P. Schlosser paper (2016)''. It should be referenced on page 45, line 23.
- As mentioned by the authors of this report, two parameters (i.e., VMAXC_MKP and KM_TPNG) are very sensitive.

- Rather than just mentioning it, the authors should further discuss these two parameters in the report. In addition, a sensitivity analysis of these two values should be included in the Sensitivity Analysis section, but they are not.

Dale Hattis, Ph.D.

First, given that these parameters are important determinants of the ultimate behavior of the pharmacokinetic model, it is a serious mistake to represent them as point estimates without estimates of either uncertainty nor variability distributions and analyses of the implications of these for policy-relevant outcomes.

The affinity of the symporter for iodide (KM_TPNG) appears to have been derived by picking a value and subjectively evaluating fit to the Greer data (App-11, Figure B-5). The new value clearly provides a better fit than the older value which was apparently based on fitting only the lowest point in the Greer data set. However, it seems to me that the fit could and should be further improved by a formal minimization of the statistically weighted departure of the model predictions from the data. Generally, the weighting for the data points should be based on the inverse of the uncertainty variance in either linear or log space depending on whether the sources of the errors in the data appear to be combine in an additive or a multiplicative way

Angela M. Leung, M.D., M.Sc.

Comments regarding modifications to existing models:

The modifications as summarized on pages 44-45 and Appendix B were reviewed. The two main modifications were the reduction of the affinity constant (Km) for the binding of perchlorate to NIS and the increased Vmax value for the transport of perchlorate from mammary plasma to breastmilk. This technical modeling aspects of this report are not my area of expertise, and thus I cannot comment on whether these are scientifically supported and/or reasonably estimated.

Michael H. Lumpkin, Ph.D., DABT

The justifications for modifying the NIS Michaelis-Menton constant (KM-TPNG) downward and adjusting blood-to-milk perchlorate transport velocity (VMAXC_MKP) using more robust data are sufficiently supported in the model report by the available data. Given the model structure changes required to align the perchlorate PBPK and iodine BBDR models, the need to revisit the model's fidelity to replicate the Greer et al. data was warranted. EPA noted that the non-pregnant female ("adult") model does not adequately replicate the RAUI behavior reported by Greer et al. for perchlorate doses above the RfD POD of 7 µg/kg/day. The strategy to begin by comparing the resulting Vmax values obtained for the older models using graphical methods to transform the data to linear relationships (as was done by Kosugi et al. [1996]) with novel fitting of the Kosugi et al. *in vitro* data using modern non-linear fitting techniques makes sense. The newly fitted Vmax value resulted in far better concordance of the model-predicted RAUI for non-pregnant women with the Greer et al. data. The EPA approach to testing the

performance of the lactating mother model with the revised KM-TPNG value was also reasonable, utilizing gestation week 38 iodide burdens as the initial conditions to simulate the Greer et al. experiment.

The use of the newer and more robust breast milk/urinary perchlorate concentration data of Kirk et al. (2013), compared to that of Tellez et al. (2005) to calibrate the rate of transport of perchlorate and iodine into breast milk was adequately justified din the report. EPA showed that the Kirk data provide more detailed and statistically powerful information with which to explore the relationship between perchlorate elimination to breast milk or urine in the lactating mother. The use of the multiplicative factor vmult to scale mammary blood flow with mammary Vmax for perchlorate adequately captured the extreme values of mammary elimination of perchlorate in the Kirk et al. study population.

Elizabeth N. Pearce, M.D., M.Sc.

The decision to eliminate the thyroid lumen as a separate model compartment seems reasonable, as does the decision to simplify the model to allow transport directly from mammary plasma to the breast milk. I also agree that it is reasonable to assume that the Km for iodine and for perchlorate are the same for NIS in the breast as they are for NIS in other tissues. It is reasonable to assume that the perchlorate urinary clearance will be the same in lactating women as in non-pregnant, non-lactating women.

The revised $Km_{NIS,ClO4}$ based on the re-analysis of the Kosugi (1996) paper is based on reasonable assumptions, however, given that the original Kosugi data were not actually available, the calibration of the model against existing datasets (see below) is particularly critical.

Stephen M. Roberts, Ph.D.

Explanations for the changes in parameters VMAXC_MKP and KM_TPNG are provided in Appendix B. The rationale and procedure for the change in KM_TPNG is reasonable and scientifically supported. The narrative describing the rationale and procedure for the change in VMAXC_MKP is more difficult to follow. Without additional explanation, I am unable to determine whether this change is scientifically supported and reasonably estimated.

Joanne F. Rovet, Ph.D.

These seem reasonable to me.

Question 3. Model calibration and sensitivity analysis: Please address the strengths and limitations of the model calibration process and the strengths and limitations of the data used for model calibration and evaluation. Identify any additional literature, data, or peer reviewed models that EPA should consider to address identified limitations.

Hugh A. Barton, Ph.D.

The strategy described for calibrating the formula fed infant first followed by the breast-fed infant and nursing mother is a logical one since the formula fed infant would be independent of the maternal parameters after birth.

Claude Emond, Ph.D.

No comment here.

Dale Hattis, Ph.D.

The fitting described in Appendix B appears to have been done without formal statistical optimization one parameter at a time, sometimes (as in the case of the Vmax value for the symporter transfer) accompanied by adjustment of another parameter, in that case the " permeability-area constant for diffusional transfer" (App 15, line 16). On the following page further individual ad hoc adjustments are described to mammary blood flow. When the values of multiple parameters are being tweaked and fits evaluated against multiple and diverse sets of observational data, I have found it to be helpful to have a much more formal search process with simultaneous variation of all the adjustable parameters and evaluation of overall fit considering the inverse-variance weighted departures of the model predictions from all the observational data sets being considered. Otherwise, the repeated adjustment of all the model parameters becomes just too complicated for me to trust my subjective judgment of fit.

Angela M. Leung, M.D., M.Sc.

Comments regarding the model calibration process and sensitivity analysis:

a. Model calibration
   - Calibration has been attempted to be done utilizing the available data from the literature regarding iodine, perchlorate, and thyroid hormone measurements in lactating women and infants. However, some of the data are misinterpreted (see my responses to Question 1B) or missing; thus, the model contains some calibration parameters that may be inexact, particularly for breastmilk and urinary iodine concentrations.
   - The statements regarding the instability of iodine levels in breastmilk on page 64 line 9 and page 82 lines 10-13 are likely misinterpretations of the personal communications with Dr. Blount, as iodine is an extremely stable element and their concentrations are unlikely to change within such short timeframes.
b. Model sensitivity analysis
   - Please see my responses below in Question 3B.

Michael H. Lumpkin, Ph.D., DABT

Strengths of the data set utilized for model calibration and evaluation include the use of data from the actual human population (including the most sensitive sub-population) for which health risks a will be evaluated. Further, the data for iodide, perchlorate, and thyroid hormone levels that was used for model evaluation are in the approximate concentration space (0-20 µg/kg/d perchlorate; 9-16 pM serum fT4) for which the model was intended *a priori*.

Elizabeth N. Pearce, M.D., M.Sc.

Strengths of the model calibrations and sensitivity analysis process include attention to validating the model against carefully-selected representative data for each life stage, and testing over a range of assumed iodine and perchlorate exposures.

It was reasonable to exclude neonatal data from the first 7 days of life in model calibrations due to the difficulty of dealing with effects of the neonatal TSH surge.

The primary weaknesses of the model calibration process was the limited nature of the datasets against which model was validated. Suggestions for additional studies are below (3A).

Leung et al. (2012) was used as the primary data source for deriving NIS-mediated uptake of iodine into breast milk. It is notable that breast milk iodine concentrations among the women in that study were extremely variable, and that the number of exclusively breastfed infants was quite small. As we concluded in that study, timing of breast milk sampling is likely one factor which explains some of the variability in measured samples; we have shown that breast milk content peaks at 6 hours after a mother ingests an iodine load. The model assumes a constant rate of iodine excretion into breast milk, which is not the case, and may complicate efforts at model calibration.

Stephen M. Roberts, Ph.D.

I will defer to other panel members on the calibration process.

Joanne F. Rovet, Ph.D.

I am not too familiar with this literature but it seems to me that most of the papers I could find are cited or authored by members of the modeling team. This is definitely an area of strength of the modelers.

Question 3A. Specifically, is the model calibration and evaluation adequately compared with what is reported in the literature for iodine and perchlorate concentrations in urine, and breast milk and thyroid hormone plasma concentrations under different iodine intake and perchlorate exposure scenarios? Please identify additional studies that would support model calibration that strengthen the proposed model.

Hugh A. Barton, Ph.D.

The model simulations shown in Figures 4 – 9 seem reasonable with some of the discrepancies as described in the report.

A challenge for this calibration is that there are other factors contributing to the observed population variability that are not incorporated into the model (e.g., variability in PK determinants like NIS for iodide and perchlorate handling, variability in thyroid hormone production and clearance, variability of intake for other NIS inhibitors potentially in diet or other sources). However, trying to add the variability into the model would only make sense if it appears to reasonably capture the average behaviors. Like any biologically based model attempting to simulate data across a wide range of endpoints from studies with different designs, some simulations are better than others. It is challenging to understand how well the available data determine the parameters that were fitted without doing a sensitivity analysis for each endpoint and study design. The variability may be important in that several studies did not find correlations among iodine and/or perchlorate levels and thyroid hormone levels (in either urine or plasma for different study designs) suggesting that other factors were contributing. The model has a deterministic description of perchlorate inhibition of iodine transport and the impact on thyroid hormone levels, so this could be perceived to be at odds with the data. It seems plausible, however, that there are other factors (some noted above) contributing to the variability that obscure relationships among iodine, perchlorate, and thyroid hormone absent exact accounting for co-variates or other approaches for population variability. This will make it challenging to use the modeling to establish a health protective level challenging and maintaining the credibility of the analysis. As noted, the easy answer, also suggested in some of the public comments, is to further expand the model to include these sources of variability, but that may not be so easy to do and demonstrate that the results are more strongly supported than the current analyses. This is an area that would benefit from at least qualitative discussion and clear acknowledgement of current limitations of the modeling, though there are not necessarily easy alternative approaches to apply that have fewer limitations.

Claude Emond, Ph.D.

I did not find any additional literature that may further support the authors' research regarding this model. I believe this report contains the major publications available.

Dale Hattis, Ph.D.

I think not. There needs to be a much more formal process of comparison of model predictions and observed data. Uncertainties in the data should be modeled and expressed as confidence limits, and summarized for comparison with model predictions.

Angela M. Leung, M.D., M.Sc.

Comments regarding model calibration and evaluation under different iodine and perchlorate scenarios:

Figures 4-9 report the model calibration results compared to data in the literature for iodine and perchlorate concentrations in urine and breastmilk and of serum thyroid hormone concentrations under different iodine intake and perchlorate exposure scenarios. As noted in my responses to Question 1B, there are some additional studies that should be reexamined and/or included to strengthen the calibration. Some specific comments are as follows:

- Figure 4 (Urinary iodine and perchlorate for formula-fed infants): It is reassuring that the model-predicted urinary iodine concentrations for formula-fed infants assumed to consume infant formula with the lowest iodine content (108 mcg/L) was within the range of urinary iodine concentrations range reported in the literature for infants fed both cow milk-based and soy-based infant formulas, but as mentioned previously, additional studies could be included regarding the iodine content of infant formulae. For infant formulas with the highest iodine content (384 mcg/L), model-predicted urinary iodine concentrations were only within the range of those consuming cow milk-based formula, which is reasonable. Model-predicted urinary perchlorate concentrations were within the range of those reported in the literature for the perchlorate content of cow milk- and soy milk-based infant formulas.
- Figure 5 (Urinary iodine for breastfed infants): The model-predicted urinary iodine concentrations for breastfed infants are also within the range of those reported in the literature at postnatal days 45-90, although as noted previously, there are limitations to the calibration of breastmilk and urinary iodine concentrations used in the model. Average maternal perchlorate dietary intake was estimated and assumed to be 100 ng/kg/day for these calibrations. Also noted is that the model for urinary iodine in breastfed infants is not within the range of literature data for postnatal days 7-44, a similarly critical period of rapid infant neurodevelopment.
- Figure 6 (Urinary perchlorate for breastfed infants): These calibrations appear to be reasonable and within the range of literature-reported values among both formula-fed and breastfed infants from postnatal days 0-90, although as noted previously, there are limitations to the calibration of breastmilk and urinary perchlorate concentrations used in the model. Maternal dietary iodine intake between 75-250 mcg/day had no effect on predicting urinary perchlorate concentrations in their breastfed infants.
- Figure 7 (Breastmilk iodine and perchlorate): The potential issues of calibration against the published literature data is summarized above in Question 1B regarding the significant variability of breastmilk iodine content in relation to dietary iodine intake.

- Figure 8 (Maternal serum TT4 and FT4): The model-predicted values are comparable to existing literature from NHANES cohorts, but significant limitations include the lack of assessment of thyroid autoantibody positivity and other variables (see my responses to Question 1B), as well as the extremely small size of this cohort upon which the model is based. Model simulations were performed for maternal dietary iodine intakes from 75-250 mcg/day and an assumed maternal perchlorate exposure of 100 ng/kg/day.
- Figure 9 (Serum TT4 and FT4 for breastfed infants; no literature available for formula-fed infants): The model-predicted serum thyroid hormone values are comparable to existing literature, although as noted previously, there are limitations to the calibration of serum thyroid hormone concentrations used in the model. Although a maternal dietary intake of 75 mcg/day predicts serum TT4 and FT4 concentrations much lower than those for higher dietary iodine intakes (150-250 mcg/day), the serum thyroid hormone concentrations of their breastfed infants remain within the range during postnatal days 7-90.

Michael H. Lumpkin, Ph.D., DABT

The model appears to adequately predict iodide, perchlorate, and thyroid hormone levels in various matrices in all of the evaluated life stages. In the lactating mother, the model captured well the observed postpartum levels of iodide and perchlorate in milk (reflecting the performance of the NIS M-M parameters, as adjusted for this model) as well as serum fT4 levels that are in the range (9-12 pM) for which dose-response analyses were recommended. The same appears to hold true for urinary iodide and perchlorate and serum fT4 simulations in breast-fed infants.

Elizabeth N. Pearce, M.D., M.Sc.

Stephen M. Roberts, Ph.D.

The process for identifying papers for calibration and evaluation should be explained more fully. Some of the exclusion criteria (e.g., mothers and infants that did not have sufficient iodine in their diets) could have eliminated studies useful for evaluating model accuracy in estimating thyroid hormone levels for individuals with low iodine intake. Also, the description of the

process indicates that 62 articles were identified that had data used for calibration, validation or setting model parameters, but concludes with the statement that "The review process was halted after it was judged that the objective had been met; i.e., sufficient data for model calibration had been identified." This suggests that articles with information potentially useful for calibration or evaluation were not considered.

Joanne F. Rovet, Ph.D.

YES for iodine and perchlorate and breast milk. NO for thyroid hormone/iodine and perchlorate. However, as I found the Results section messy and not clear, I cannot adequately judge how well the model agrees with the extant literature for iodine and perchlorate concentrations in urine and breast milk. The only study to examine these is Leung et al. (2012), which found no effect of breast milk perchlorate on infant thyroid hormone levels.

Question 3B. Are the influential parameters identified in the local sensitivity analysis for total thyroxine (T4) and free thyroxine (fT4) plasma concentrations consistent with known biology? Are there critical data gaps for the influential parameters, which would impact the thyroid hormone predictions? If gaps are identified, please provide approaches that would improve thyroid hormone predictions.

Hugh A. Barton, Ph.D.

This reviewer cannot comment on whether the "influential parameters" are "consistent with known biology". There are descriptions in Tables 4 and 5 of the basis for the values for these influential parameters and there does appear to be some data available for each, though it is difficult to evaluate how well it determines each parameter.

Claude Emond, Ph.D.

The sensitivity analysis (SA) discussed in the report tested the influence of the new parameters, which were also described for the iodine description, and discussed whether there was a presence of exogenous perchlorate and iodine. The analysis and synthesis performed in this report are not descriptive enough. The report should include more detailed discussions so the readers will understand the impact of each parameter. Currently, based on the SA each parameter seems to have a similar impact in the prediction of the model. It is difficult to extract the sensitive parameters that drive the simulation.

Dale Hattis, Ph.D.

The influential model parameters seem to have been identified, but I am not satisfied with the generally subjective procedures used to judge whether the existing set of parameter values leads to model predictions that reasonably correspond to model predictions, or whether better model predictions are possible using improved sets of parameter values.

Angela M. Leung, M.D., M.Sc.

Comments regarding sensitivity analyses for serum TT4 and FT4 concentrations:
The analyses reported on pages 83-91were reviewed, from which the main findings are summarized as below.

- Results for infant serum TT4 and FT4 concentrations are identical, and thus only infant serum T4 concentrations are reported.
- Influential parameters were time-dependent, iodine-dependent, and perchlorate-dependent.
- Given the relatively lower iodine content in breastmilk, as compared to infant formula, the effect of perchlorate exposure was more significant in the analyses which examined perchlorate exposure from breastmilk.

These findings are generally consistent with the available knowledge regarding factors which may influence serum thyroid hormone concentrations. However, as described in my response to

Question 4A, it would be prudent to also examine the influence of serum thyroid autoantibody positivity on serum thyroid hormone concentrations in these sensitivity analyses.

Michael H. Lumpkin, Ph.D., DABT

Although the report states that the most influential parameters are time-, iodide-, and perchlorate-sensitive (p84), Figures 19-20 and Tables 11-12 do not seem to support this, except for the day 7 influence for both formula and breast-fed infants. The influence of daily T4 production (VPRODT4CX) and 1st order T4 clearance (CLMETT4CX) parameter values have far more impact than parameters that influence perchlorate-related changes to iodide transport into the thyroid and breast milk, which is surprising. If that is the case for this model, some discussion in the report of why that is the case may be helpful.

Elizabeth N. Pearce, M.D., M.Sc.

Sensitivity analyses used to determine influential parameters for total and free T4 concentrations in formula- and breast-fed infants included a range of iodine exposures (from 75-200 mcg daily for mothers and breastfed infants, and from 108-384 mcg/L formula for the formula-fed infants) and of perchlorate exposures (from 0-20 mcg/kg/day) for both mothers and infants. The range of perchlorate exposures chosen for testing seems reasonable. It should be noted that there is a very wide range of allowable infant formula iodine content for full-term infants in the U.S: 5 to 75 µg/100 kcal (33.5–507.2 µg/L) (U.S. Food and Drug Administration 2006Code of Federal Regulations 21CFR107 Infant formula. [HYPERLINK "http://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfcfr/CFRSearch.cfm?CFRPart=107&showFR=1"]). Therefore, the sensitivity analyses did not account for potentially much lower iodine exposures in formula-fed infants which presumably could occur in the U.S.

It is logical that rates of T4 to FT4 conversion, rates of T4 production in the infant thyroid, and rates of thyroid hormone metabolism would be the highly influential parameters for the FT4 models. In the breastfed infants, the influence of intrathyroidal iodine stores (CTGIPOOL_N) is a stronger influence at day 7 of life than at day 90; this makes sense in light of the fact that intrathyroidal iodine turnover is highest in the immediate neonatal period.

Stephen M. Roberts, Ph.D.

The results of the local sensitivity analysis are cryptic at best. Normalized sensitivity coefficients are presented in graphical and tabular form for parameters listed in coded form. There is virtually no discussion of parameters identified as influential, other than to say "influential parameters were time-dependent, iodine-dependent, and perchlorate-dependent." It would in fact be useful to clearly identify what are regarded as influential parameters and to discuss in the report whether they are consistent with known biology, but that is missing. As presented, the sensitivity analysis will have little value for most readers.

Joanne F. Rovet, Ph.D.

I am not able to answer this given the way the information is presented. I would have liked a closer match between the categories in Table 7 and the models in Figures 2 and 3.

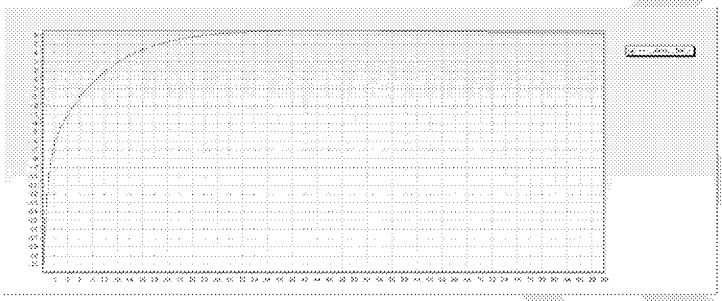
Question 3C. Does the proposed model provide the appropriate level of precision and substantiated support for this approach? Please identify any additional limitations of the model's applicability?

Hugh A. Barton, Ph.D.

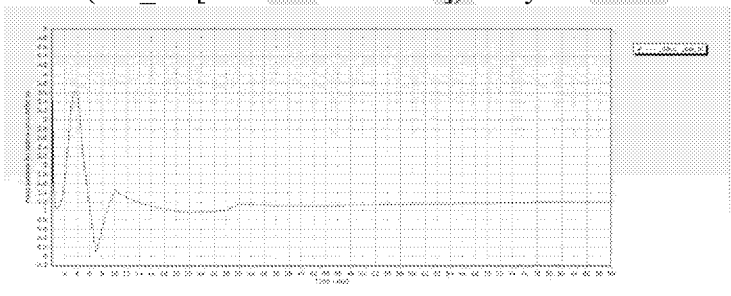
Presumably, "this approach" refers to using the model to assess potential perchlorate dose-response. Various limitations of the effort are noted in the report and the comments here.

Claude Emond, Ph.D.

The mass balance for the maternal iodine (Bal_i [see line 1561 of the code in acslX]) should be checked (see the figure below). For iodine, the mass balance is probably a minor error, but it should be corrected.



As can be seen in the figure below, there is also an issue regarding the mass balance for the infant (Bal_Ni [see code line 1577]). Maybe a correction or justification is required.



The mass balance for the weight and the volume are both fine for the mother and the infant.
I am unsure why the authors doubled the volume and the blood flow for perchlorate and iodine?

Dale Hattis, Ph.D.

This cannot be adequately evaluated with the comparison plots provided.

Angela M. Leung, M.D., M.Sc.

Comments regarding model precision:

There are several limitations, as mentioned elsewhere in this report, which may limit the precision and substantiated support of the model.

In addition, there was a recent publication estimating the perchlorate burden from dietary intake as part of the FDA's Total Diet Study (Abt E et al, PMID 28000685), which can be cited to support the range of perchlorate exposure levels assessed in the model.

Michael H. Lumpkin, Ph.D., DABT

The performance of the model in replicating concurrent milk and urine iodine and perchlorate data in the lactating mother, and perchlorate and serum fT4 in the breast-fed infant in the space of perchlorate exposure and thyroid hormone levels for which that model is intended be utilized indicates sufficient precision of the model for use in dose-response assessment.

Elizabeth N. Pearce, M.D., M.Sc.

I do not have expertise in model development, so I am unable to comment on this question.

Stephen M. Roberts, Ph.D.

It is difficult to determine from the report whether the model provides the appropriate level of precision and substantiated support for this approach. As presented in the report, model predictions of various outputs (e.g., urinary perchlorate, urinary iodide) typically fall within or near a broad range of values reported in the literature. One interpretation is that the model is consistent with empirical observations in humans. Another interpretation is that the model predictions could be substantially different and still be consistent with the literature given the variability observed there. This problem is not easily solved, as studies providing actual measurements are likely to have influences in play that contribute to the substantial variability that is observed, but are poorly understood and therefore cannot be captured in the model.

Joanne F. Rovet, Ph.D.

I was not able to fully comprehend the meaning of the data in Figures 18-20 or Tables 11-12 as they contained what seemed to me to be just raw data or statistical output with little attempt to synthesize these data. No statistics are presented and the Figures lack legends that might allow one to zero in on key findings. Global comparison of the three figures suggests to me a greater impact of perchlorate at Day 7 in the formula-fed than breast-fed infant at the low iodine level; in the mother, this perchlorate effect took place later. I am not sure how my "eye-balling" conforms with the graphs provided.

Question 4. Hypothyroxinemic reference levels and model predictions: The SAB (2013) recommended that the EPA focus the application of BBDR modeling on the condition of hypothyroxinemia, in which circulating levels of free thyroxine (fT4) are reduced below the normal ("reference") range, but with normal levels of thyroid stimulating hormone (TSH). While the mode of action (MOA) for perchlorate is well described, a defined set of quantitative definitions for reference ranges for hypothyroxinemia during pregnancy or lactation and in infants is not available. For interpretation of the BBDR model, EPA developed a normalization procedure to derive hypothyroxinemia reference intervals and to control for the expected differences between literature results and model predictions.

Question 4A. Please comment on the hypothyroxinemia reference ranges derived for pregnant mothers, fetuses, lactating mothers, breast-fed infants and bottle-fed infants. Is the assumed range between the 2.5th and 10th percentile of the fT4 distribution reasonable? Is it supported by the available data? Has the derivation of the reference ranges, including the normalization process, been appropriately described and supported in the model and the report?

Hugh A. Barton, Ph.D.

This reviewer cannot comment on the range of iodine intake levels beyond indicating that the approach of using a range of values appears a valuable one.

Claude Emond, Ph.D.

As mentioned in page 17 of the report, there has been no consensus in the literature regarding the limit between euthyroid and hypothyroxinemia condition; therefore, determining this by using the range of fT4 is reasonable.

Dale Hattis, Ph.D.

I think these choices of reference ranges are completely arbitrary and not founded without well-grounded justification in biology. As indicated earlier, I think it would be best to use the thyroid hormone predictions from exposures to perchlorate in early pregnancy to estimate expected population-wide changes in expected IQ's for the offspring of the pregnancies. This endpoint would provide much more meaningful information for juxtaposing expected costs and benefits of regulatory actions to alter perchlorate exposures.

Angela M. Leung, M.D., M.Sc.

Comments regarding hypothyroxinemia reference ranges:

Page 17 (lines 12-21) outlines the model's definition of hypothyroxinemia, which are described as serum FT4 concentrations for pregnant mothers, lactating mothers, breastfed infants, and formula-fed infants in the 2.5-10th percentile of the general population. Euthyroxinemia in the model is defined as serum FT4 concentrations in the 10-90th percentile. The selected reference range for hypothyroxinemia also assumes that overt hypothyroidism (i.e., an elevated serum TSH concentration with low serum FT4 concentration) occurs when serum FT4 concentrations are in the <2.5th percentile range. These parameters were chosen due to a lack of a universal definition for hypothyroxinemia in these population subgroups from the available literature. The following are some considerations, particularly regarding the limitations surrounding the definition of hypothyroxinemia during pregnancy:

- Thyroid hormone levels are dependent on the prevalence of thyroid autoantibodies in the population examined, which was not accounted for in the current model. Positive thyroid autoantibodies carry up to a 5-fold risk of hypothyroidism in geographic regions of iodine sufficiency (Moleti M et al; PMID 19179457).
- The accuracy of serum FT4 immunoassays in pregnancy has been questioned (Lee RH et al; PMID 19114271), due to their dependence on thyroid binding proteins.
- A recent review provides a comprehensive summary of this topic during pregnancy and should be included as a reference (Negro R et al; PMID 21247845).

Michael H. Lumpkin, Ph.D., DABT

The review of Moleti et al. (2011) cites 10 published studies of pregnant women in which threshold hypothyroxinemia was defined as the 2.5th or 10th percentile of fT4 in the respective cohort. As pointed out in the report, the fT4 levels represented in these percentiles are variable, likely being owed to cohort-specific fT4/TSH characteristics or differences in laboratory analytical capabilities brought to bear on each cohort's analysis of thyroid hormones. The normalization of study-specific thyroid hormone means for euthyroid and hypothyroid women is justified in order to use a single BBDR model to be used for dose-response analyses based on disparate data sets. The normalization procedure described in the report appropriately adjusts the "normal" and hypothyroxinemic ranges reported in the literature.

Elizabeth N. Pearce, M.D., M.Sc.

The existing literature regarding effects of maternal hypothyroxinemia in pregnancy variably uses thresholds of the 2.5th, 5th, or 10th percentile to define the condition. Therefore, I think this range is reasonable in pregnancy. A similar normalization approach for maternal thyroid function across different assay platforms has recently been described: Bestwick JP, John R, Maina A, Guaraldo V, Joomun M, Wald NJ, Lazarus JH. Thyroid stimulating hormone and free thyroxine in pregnancy: expressing concentrations as multiples of the median (MoMs). Clin Chim Acta. 2014;430:33-7.

There is currently no accepted clinical definition of isolated hypothyroxinemia outside of the pregnancy setting. In the absence of an accepted definition at these life stages, using the 2.5th to 10th percentile of the fT4 distribution is reasonable.

Stephen M. Roberts, Ph.D.

The SAB Perchlorate Advisory Panel noted the following in their report: "Perhaps most critical are the findings from studies examining the effects of isolated maternal hypothyroxinemia, defined as a free thyroxine (fT4) value in the lower end of the normal range with normal levels of TSH. This research has involved a variety of cutoffs to signify maternal hypothyroxinemia ranging from fT4 below the 10th or 5th percentiles to below the 2.5th percentile (Moleti et al. 2011), with the former percentiles being used to investigate neurodevelopmental outcomes and the latter the incidence and effects on pregnancy (e.g., Casey et al. 2005). Children exposed gestationally to maternal hypothyroxinemia (without hypothyroidism) show reduced levels of global and specific cognitive abilities, as well as increased rates of behavior problems including greater dysregulation in early infancy and attentional disorders in childhood (Man et al. 1991; Pop et al. 1999; Pop et al. 2003; Kooistra et al. 2006). Notably these effects are correlated with both degree (Pop et al. 1999; Henrichs et al. 2010) and duration (Pop et al. 2003) of maternal hypothyroxinemia. The Henrichs (2010) study, which stratified children into severe (<5th percentile) and mild (5-10th percentile) maternal hypothyroxinemia subgroups, showed that while effects were stronger and broader in the severe subgroup, the mild subgroup still showed delayed language development, thus suggesting that any factor that lowers maternal fT4, even slightly, can affect the offspring." (SAB 2013; pg. 10). The assumed range between the 2.5th and 10th percentile of the fT4 distribution is reasonable and consistent with the discussion presented by the SAB panel for pregnant women relative to risk to the fetus. However, as discussed in response to charge question 1C, modeling fetal thyroid hormone changes is unnecessary and problematic. Also, no rationale is presented for modeling fT4 in lactating women — they are not a sensitive life stage — and the relevance of determining an appropriate range for fT4 in these individuals is therefore unclear.

Understanding thyroid hormone changes in breast-fed and bottle-fed infants is important, but a clearer case needs to be made why the range between the 2.5th and 10th percentile of the fT4 distribution is appropriate. Are there empirical observations to support this range as associated with increased risk of impaired neurodevelopment in neonates and infants, or is it selected on another basis (e.g., as a matter of consistency with maternal hypothyroxinemia and risk to the fetus, or simply as a conservative choice)? Some discussion of the extent of diminished thyroid hormones in neonates and infants associated with neurological impairment (e.g., studies of transient hypothyroxinemia of prematurity and children with congenital hypothyroidism) might be helpful in providing perspective [Note: The SAB panel encouraged the EPA to examine this literature as part of an effort to better understand thyroid hormone disruption associated with adverse effects on neurodevelopment.]

Joanne F. Rovet, Ph.D.

I disagree with this reference range. Most studies (of mothers) use a value below the 5th percentile and when studies do examine mother-child pairs with maternal values up to the 10th percentiles, these are done in a correlational design with results showing no or very mild effects for offspring of mothers with mild (i.e., 5th to 10th percentile) hypothyroxinemia. I would also like to see effects of values below 2.5th percentile and the impact on subclinical or compensated hypothyroidism. It is not a given that TSH is elevated when fT4 is below the 2.5th percentile nor

not elevated when above this value. There are to my knowledge no reference levels for hypothyroxinemia in infants.

Note that I was one of the writers of the cited section of the SAB-PAP report. Rereading the section and recalling the discussion, it wasn't that these findings (i.e., hypothyroxinemia) were more critical than those on subclinical hypothyroidism; rather, these findings were relevant in that even a low fT4 with a normal TSH, particularly when the fT4 was below the 5th percentile, had consequences for later offspring outcome. In other words, this interpretation is taken out of context. Furthermore, the decision to exclude TSH seems to be based totally on an old (1981) paper by Silva and Silva, I believe from Chile, and this needs to be supported by more recent evidence.

Question 4B. Model predictions for zero intake of perchlorate indicate the range of iodine ingestion for which these life-stages are expected to be euthyroid vs. hypothyroxinemic. Are these predictions reasonable and have they been appropriately described and supported in the model and the report?

Hugh A. Barton, Ph.D.

This reviewer cannot comment on the range of iodine intake beyond noting that the descriptions in the report appeared clear.

Claude Emond, Ph.D.

The predictions and descriptions are appropriate to support the model.

Dale Hattis, Ph.D.

As far as I can tell at this stage, there is every expectation that some people in iodine deficient areas and elsewhere will be hypothyroxinemic at zero perchlorate exposure. This should be checked against actual NHANES data and juxtaposed with information on local water perchlorate levels in the areas where the NHANES subject resided.

Angela M. Leung, M.D., M.Sc.

Comments regarding the effects of zero perchlorate exposure and iodine ingestion on serum thyroid function:

Perchlorate exposure will invariably co-occur with other thyroid toxicants, many of which are similarly ubiquitous and also have inhibitory effects on iodine at NIS. The best well-described known examples are thiocyanate and nitrate, and their effects should be included in the model. As such, zero perchlorate exposure cannot necessarily be assumed to result in serum thyroid function changes resulting from iodine intake alone, but rather as a combined result from other coexposures and iodine intake. However, of these three known NIS inhibitors, perchlorate has been demonstrated to have the strongest effect in competitively inhibiting iodine uptake at NIS (Tonacchera et al; PMID 15650353).

Michael H. Lumpkin, Ph.D., DABT

The ranges of euthyroid (<100 µg/day) and hypothyroxinemic (75 µg/day or less) iodide intake levels for the BBDR model are appropriately described in the report. The report repeatedly warns of the uncertainty in model predictions of fT4 levels at iodide levels in the hypothyroxinemic range, as TSH-mediated regulation of iodide transport and T4 production are expected to be activated.

Elizabeth N. Pearce, M.D., M.Sc.

Figures depicting the dose-response curves for free T4 across perchlorate exposures are challenging to interpret as currently presented. However, it is noted on page 18 that at 75 mcg/day iodine ingestion pregnant and lactating women are assumed to be hypothyroid, and that at <100 mcg/day iodine intake the fT4 approaches the lower end of the maternal reference ranges even in the absence of perchlorate exposure. In reality, the literature demonstrates that at those iodine intakes there is a wide range of maternal thyroid function values, likely reflecting substantial intraindividual variations in adaptive capacity, and although median TSH might be higher in populations of pregnant or lactating women with iodine ingestion 75 mcg/L than in those with adequate iodine intakes, the vast majority of women likely would not be hypothyroid. It is for that reason, that serum TSH, free T4, and T3 are considered highly insensitive as biomarkers for population or individual iodine status in adults, including pregnant and lactating women (Pearce EN, Caldwell KL. Urinary iodine, thyroid function, and thyroglobulin as biomarkers of iodine status. Am J Clin Nutr. 2016;104 Suppl 3:898S-901S). This is, in part, which I think it is important to include the full HPT axis in the models.

For breastfed infants, if 75 mcg/day maternal iodine ingestion was assumed for pregnancy and maternal intake in lactation was <100 mcg/day, the model suggests that FT4 is low even in the absence of perchlorate exposure. This assumption may be overly conservative, but is reasonably well supported by data in the report.

Stephen M. Roberts, Ph.D.

Providing model predictions of fT4 levels with zero intake of perchlorate should provide an opportunity to check the accuracy of predictions, but unfortunately there are few studies relating iodine intake and fT4 levels in the life stages of interest. For example, the modeling predicts that a pregnant or lactating woman with 75 µg/d iodine intake and no perchlorate exposure will be hypothyroid. I found no study that indicates whether or not this prediction is plausible, and the report itself provides no discussion of the reasonableness of the estimates. So, while the predictions are described, they are not supported [as valid] in the report.

Joanne F. Rovet, Ph.D.

I don't understand the question. Hypothroxinemia in the 5-10% range is not to me a problem of concern for the developing infant. There are no data examining infant fT4 levels in this range and later outcome. Note: most concern for later outcome has generally reflected the maternal state throughout pregnancy and not the neonatal state in children who do not have congenital hypothyroidism. However, a recent study by C Trumpff et al. (2016, Frontiers in Endocrinology) that examined the relationship between elevated TSH levels at birth and preschool-age behavior problems in an area of mild iodine deficiency reported no association. Further, Oken et al. (2009, JCEM) studying the relationships between neonatal fT4 levels (all levels) and subsequent abilities reported an *inverse* relationship with visual recall at 6 months and no relationship with language or visuomotor development at age 3 years.

Question 4C. Based on the perchlorate level at which each life stage is predicted to become hypothyroxinemic (for a given iodine ingestion rate), it appears that the lactating mother is more sensitive than the breast-fed infant for PND 30-90. In part, this occurs because breast feeding reduces the iodide available for the maternal thyroid. Are these predictions reasonable and have these predictions been appropriately described and supported in the model and the report?

Hugh A. Barton, Ph.D.

This reviewer cannot comment on the reasonableness of these predictions, though they appear well described in the report. Perhaps part of evaluating the reasonableness is to ask what the implications of hypothyroxinemia are for the lactating mother versus the breast-fed infant. For the infant, the concern would be impacts on neurodevelopment. Is the issue for the lactating mother, a direct impact on her heath or a concern for inadequate levels of iodine and/or thyroid hormones in breast milk for the infant? If the former, then the lactating mother's sensitivity would be an endpoint to consider, but if it is the latter, then despite the apparently greater sensitivity of the mother, the direct predictions for the infant would seem more relevant.

Claude Emond, Ph.D.

The prediction of the model is reasonable based on the prediction presented in the report (see Figures 4, 5, 6, and 7). This is true for the mother and infant prediction during lactation or none. However, there is a lack of data, so we do not have enough information to qualify the risk for the fetus. The authors of this report expressed very well the limitation and applicability of this model (pages 16 to 22). Also, it seems that the influence of perchlorate, iodine or both exposure has a higher impact from exposure to perchlorate during breast feeding.

Dale Hattis, Ph.D.

This seems reasonable. However, it is best evaluated by drawing on the empirical information generated with the information assembled via my response to question 4B, separated by pregnant vs lactating women subgroups.

Angela M. Leung, M.D., M.Sc.

Comments regarding hypothyroxinemia in the lactating mother at PND 30-90:

- Breastfeeding does require a greater available iodine supply to the mother, and thus the U.S. Institute of Medicine recommends a slightly higher Recommended Dietary Allowance (RDA) of iodine during lactation then pregnancy (although the WHO/UNICEF/IGN just recommends an overall higher daily intake during both pregnancy and lactation, compared to the non-pregnant, non-lactating adult).
- Assuming that this is the primary mechanism for the increased vulnerability of the lactating mother, it should be anticipated that the prediction would also hold true for the entire postnatal duration studied in the model, which is not suggested. Thus, model calibration parameters may be still be inexact in the model's present form.

Michael H. Lumpkin, Ph.D., DABT

The conceptual reasoning given in the report that the lactating mother is more sensitive than the breast-fed infant because of additional iodide loss to the milk is biologically plausible. However, the report could include plots of simulations showing this relationship. For example, plasma iodide plotted against breast milk iodide levels across gestation, particularly at lower iodide intake rates, could illustrate this suggested phenomenon.

Elizabeth N. Pearce, M.D., M.Sc.

It is true that secretion of a significant amount of iodine into breast milk has the potential to make iodine unavailable for the lactating woman's own thyroid, a problem potentially exacerbated by the high dietary iodine requirements in lactation, as well as by perchlorate exposure. However, in thinking about populations sensitive to the effects of perchlorate, the concern with regard to lactating women does not pertain to their own hypothyroxinemia, but to the potential for inadequate supply of iodine in the breast milk, with potential adverse consequences for the thyroid hormone status and, ultimately, neurodevelopment of the breastfed infant. Therefore, as above, I think the concept of modeling maternal hypothyroxinemia in the lactating mother herself is somewhat flawed. It doesn't really make sense to describe the lactating mother as more sensitive to the effects of perchlorate than her breastfed infant at days 30-90 since transient maternal hypothyroxinemia over that time frame likely would not have long-term consequences for the mother, but could for the infant. Clinically, in the U.S. we do not see a higher-than-usual incidence of maternal hypothyroidism in lactation, (outside the setting of autoimmune postpartum thyroiditis), which does suggest to me that the model's predictions may not be correct. Calibrating the lactating women model against a more robust dataset may help to determine whether hypothyroxinemia is truly more likely to develop in lactating women than in their infants.

Stephen M. Roberts, Ph.D.

It is argued that the model result indicating that the lactating mother is more sensitive to hypothyroxinemia from perchlorate than her breast-fed infant is plausible because breast-feeding reduces iodine available for the maternal thyroid. This appears to be largely speculation. Appendix F includes a comparison of fT4 between lactating, pregnant, and "all other" women using data from NHANES. Although the fT4 levels in lactating women appear to be lower than "all other women", levels in pregnant women are even lower. I am not aware of any evidence from the literature that breastfeeding increases the risk of thyroid deficiency (even subclinical) and none is provided in the report. It is possible that this finding indicates a problem with the modeling of fT4 in the lactating mother, the breast-fed infant, or both.

Joanne F. Rovet, Ph.D.

I am not aware of any data to support this prediction. I am also not aware of any data comparing thyroid hormone levels of breast-feeding and formula-feeding mothers.

Question 5. Robustness of model predictions and sensitivity at lower perchlorate dose levels:
The dose-response predictions from the BBDR model predict levels of fT4 for:
a) The pregnant mother and fetus at GW40 (Fig. 10);
b) The formula-fed infant with fixed (Fig. 11, 7 and 30 day infants) and variable (Fig. 12, 7 through 90 day infants) iodine levels in their formula; and
c) The breast-fed infant as a function of maternal perchlorate exposures and iodine ingestion (Fig. 13, 7 through 90 day infants).

For each of these subgroups, please characterize the extent of uncertainty along the dose-response curve. In particular, is the level of uncertainty acceptable at lower dose levels of perchlorate (e.g., at or below 4 µg/kg/d) and higher levels of iodine intake (e.g., 150 µg/d) for each of these subgroups (left upper corner of the dose-response curves)? Should EPA assume that the model becomes more uncertain with rising perchlorate dose levels and declining iodine ingestion, i.e., as model predictions for fT4 approach and move through the range of hypothyroxinemia. (It should be noted that calibration of the iodide and thyroid hormone sub-models used data for populations with higher iodine intake and background exposure to perchlorate.)

Hugh A. Barton, Ph.D.

For formula-fed and breast-fed infants, there were some data on urinary perchlorate in the 1 – 10 µg/L range that appears to somewhat inform lower perchlorate intake levels though it is difficult to assess how well it constrains the dose-response behavior of the model. It seems likely that the models becomes more uncertain with higher perchlorate exposures that result in greater inhibition and lower iodine levels, which at some point become hypotheyroxinemia with elevated TSH that the model explicitly does not address.

Claude Emond, Ph.D.

These figures generated with the two PBPK models seem convincing that the models are sensitive enough inside of clinical range. However, they need now to be compared to the relevant exposure source of perchlorate in water.

Dale Hattis, Ph.D.

Again, I think these model predictions are best evaluated with empirical NHANES data separated into geographic categories by estimate levels of perchlorate in water. Because I am unconvinced by the calibration of the model as indicated earlier, I don't entirely trust the model predictions and have no basis to evaluate how much they are likely to be off.

Angela M. Leung, M.D., M.Sc.

Comments regarding model predictions and sensitivity at lower perchlorate levels in:
Figures 10-13 were reviewed with specific focus on the curves for lower perchlorate exposure and higher dietary iodine intake levels (left upper corner of the dose-response curves). In accordance with some of the public comments submitted thus far, it is reasonable to consider not including those which calibration for the iodine and thyroid hormone submodels were not performed for, given the non-linear interdependence of iodine status with thyroid function –a relationship which is further complicated with the exposure to varying NIS inhibitors, including perchlorate. It is reasonable to assume that the models may be more uncertain for these areas which have not been calibrated for in the report.

Michael H. Lumpkin, Ph.D., DABT

With the exception of the formula-fed infant life stage, the assumption that the model predictions of fT4 become more uncertain as perchlorate exposure increases and iodide intake decreases appears to hold, particularly for the pregnant mother, based on the increasing proportion of the dose-response curves that move below the normalized 2.5th percentile level.

Elizabeth N. Pearce, M.D., M.Sc.

I think it is reasonable to assume for all of the models that there is a higher degree of uncertainty at both lower iodine and higher perchlorate exposure levels. There is likely less uncertainty in the formula-fed infant model, given that only adequate iodine intakes are assumed.

Stephen M. Roberts, Ph.D.

The model is predicated on the absence of a compensatory response throughout the predicted range of fT4 levels. This assumption becomes more tenuous with lower predicted fT4 levels, thus uncertainty in the results increases. Public commenters have argued that compensatory responses may in fact occur even within the hypothyroxinemia range that is the focus of this model, and that this needs to be incorporated into the model. I have not seen a clear presentation of data to support this contention, but it is an issue that should be addressed directly one way or another in the presentation of the model.

Joanne F. Rovet, Ph.D.

a) First, what is GW40? – I assume it is parturition at 40-weeks gestation. Sorry, defined in figure caption, but should be listed in list of abbreviations. I found Figure 10 hard to interpret as the lines weren't clearly distinct from each other. I presume everything that is grey is bad and this includes most iodide exposures when perchlorate exceeds 11.7 pM. As I can't make sense of "uncertainties" from this graph (an assumed knowledge that I lack), I cannot comment. However, one doesn't need a model to know that low iodine compounded with high perchlorate is bad based on the literature and clever extrapolations of the epidemiologists on the SAB-PAP panel. My concern is the assumption that the 40-week gestation pregnant mother represents all

of pregnancy when we know that all thyroid hormones change during different trimesters of pregnancy and the impact of insufficiency in early pregnancy may be more serious than later.

b) My concern here is neglecting the measurement of perchlorate in the water used to make formula for older infants. Also, it is not clear to me why there is an impact at day 7 in formula-fed infants. Wouldn't any contribution from mother have vanished by this time in light of the Vulsma et al. (1989) study.

c) As I am having much difficulty understanding and seeing the essence of each graph, I cannot comment here.

Question 6. Empirical functions to predict thyroid hormone levels: The pregnancy model (but not the lactation/infant models) uses empirical functions to make urinary clearance of iodine and metabolic degradation of T3 dependent on the iodine ingestion level, in order to predict observed nonlinearity in the relationship between thyroid hormone levels and iodine intake. Does this use of empirical functions result in predicted outcomes or trends that are not plausible for serum thyroid hormones, particularly fT4?

Hugh A. Barton, Ph.D.

This reviewer cannot comment on whether the predictions for serum thyroid hormones are plausible.

Claude Emond, Ph.D.

Empirical function is a good alternative when we do not have more information about biological observations. During many situations, the model was described by using a table function that showed biological observations by using an empirical distribution. The result provides an approximation of the plausible observation of the parameters. During the simulation performed in the context of short exposure, such as 90 days, the result is acceptable. However, to simulate the impact of lifetime exposure, repetitive gestation, or acyclic lactation, I think it would be better to express variations of the parameters.

Dale Hattis, Ph.D.

I can't tell from the information I have available.

Angela M. Leung, M.D., M.Sc.

Comments regarding empirical functions in the pregnancy model:

The pregnancy model as reported in Lumen et al 2013 (including Tables 2 and 3 and their corresponding text) was reviewed in relation to this question. The functions used in the pregnancy model regarding the urinary iodine clearance and metabolic degradation of T3 are supported by the trimester-specific calibration parameters used. The predicted outcomes and trends for serum FT4 concentrations, as presented in the pregnancy model, are plausible and in line with those reported for the high perchlorate exposure ("Taltal") group in the Tellez R et al 2005 report.

Michael H. Lumpkin, Ph.D., DABT

The use of empirical relationships to describe urinary iodine clearance and T3 degradation does not, based on the model performance shown in the report, appear to result in implausible thyroid hormone levels.

Elizabeth N. Pearce, M.D., M.Sc.

Urinary clearance of iodine in pregnancy is largely a function of glomerular filtration rates since iodine is believed to be largely passively excreted at the kidney. The amount of ingested iodine will strongly influence the urinary iodine concentration, but not necessarily the fraction of plasma iodine which is renally excreted. Degradation of maternal T3 is strongly influenced by high levels of type 3 deiodinase in the placenta. I am not aware of data demonstrating that there are alterations in the placental DIO3 activity relative to differing iodine intakes. Therefore, although the empirical functions help to fit the model to observed data, they are not necessarily in line with currently understood physiology. The need to make these empiric adjustments to the model suggests data gaps which are worth exploring through future studies.

Stephen M. Roberts, Ph.D.

I will defer to other panel members on this charge question.

Joanne F. Rovet, Ph.D.

I cannot comment although the findings presented in the two Lumen et al. (2013, 2015) papers seem clearer and more robust to me than the current.

Question 7. Characterization of model predictions: The pregnancy and infant/lactation models were developed to specifically consider the range of iodine ingestion and thyroidal uptake where TSH is expected to stay in its normal range (i.e., they do not account for HPT feedback control). Do the models represent a reasonable effort to describe the relationships between iodine intake, perchlorate exposure and thyroid function? Are they sufficiently specific to predict perchlorate-induced changes in thyroid hormones in these life-stages over the range indicated? Please characterize the robustness, precision and sensitivity of the models for the ability to extrapolate changes in T4 associated with perchlorate exposures over the range from low exposures (less than 1 µg/kg/d) to higher levels which the model and analysis predict to be hypothyroxinemic.

Hugh A. Barton, Ph.D.

As noted in the general comments, this is a systems model of substantial complexity that appears to have been reasonably developed based upon available scientific information. Absent working with the models to develop a detailed understanding of their behavior, I would not try to comment on robustness, precision, or sensitivity for predictions.

Claude Emond, Ph.D.

The models represent a reasonable effort, and the authors have provided detailed descriptions; therefore, it was possible to do use the model by utilizing the current literature.

I believe these are good models (PBPK model women-fetus and women- infant) because they describe the major step of the mode of action of the hypothyroxinemic by using recent literature. I believe that this PBPK model reached the maximum of its potential based on the literature available and referenced and can be used along with the exposure observation inside the range it was established or limited. I believe that this model will further improve and become more sophisticated when more information about biological observations are included. We need to remember that a model is a simplification of biological observations. We will probably never be able to describe in the close future all of the biological mechanism processes implicated in hypothyroxinemic; however, this PBPK model can include the major pieces of limiting step in the sequential mode of action causing this effect. Here, in this model, only the effect of a supplement of iodine and the exposure of perchlorate are considered in inducing hypothyroidism; nevertheless, other physiological disturbances may also cause the issue. In addition, this model predicts the range specified by the authors. In the future, the PBPK models will need to be challenged to characterize exposure situation out of the range mentioned in the report, to gain a better understanding about the limitation of each parameter implicated in the PBPK model, and to study the impact of this model on the fetus. Specifically, the fetus might be sensitive to perchlorate, but there is not enough information to conduct a simulation like we did for infants and women.

Dale Hattis, Ph.D.

Without the improved model performance tests on calibration I have described earlier, I cannot quantitatively evaluate the accuracy of the model predictions. The modes are "sufficiently specific to predict perchlorate-induced changes in thyroid hormones in these lifestages". How accurate the predictions are is anyone's guess.

Angela M. Leung, M.D., M.Sc.

Comments regarding characterization of model predictions:

The current model and sub-models are based on the assumption that the range of perchlorate exposure doses and iodine intake levels studied would be autoregulated by the thyroid to compensate for these perturbations, and thus only serum thyroxine levels are decreased while serum TSH concentrations remain normal (i.e., hypothroxinemia is the primary endpoint). The model attempts to describe the relationships between iodine intake, perchlorate exposure, and serum thyroid function, but may be significantly influenced by the following major limitations, as has been described in greater detail in my previous comments:

- Serum thyroid hormone concentrations in pregnancy cannot be reliably extrapolated for lactation.
- Lack of serum thyroid autoantibody data, which may impact serum thyroid hormone concentrations and reference ranges.
- Variation in breastmilk iodine content in relation to recent dietary iodine ingestion.
- Calibration of the model for many crucial parameters (iodine and concentrations in breastmilk, maternal urine, and infant urine, and for infant serum thyroid function) was based on the study by Leung 2012, which did not examine women who were exclusively breastfeeding. Thus, the iodine nutrition provided to their infants was derived from a combination of both breastmilk and infant formula.
- The effects of likely coexposures from other NIS inhibitors on breastmilk and urinary iodine and perchlorate concentrations, and or infant serum thyroid function, are not addressed.

Michael H. Lumpkin, Ph.D., DABT

The model performance across the various represented life stages appears to be robust for low perchlorate exposures and iodide intake levels resulting in thyroid hormone levels above the 10^{th} percentiles for the reference ranges. Although the model is restricted to represent limited thyroid hormone homeostasis in isolation of HPT feedback mechanisms (and, possibly, compensatory corrections of iodide uptake and transport inhibition), it represents a plausible and technically justified approach to defining the perchlorate dose-response across a narrow exposure range. Given the model's isolation from the HPT feedback mechanisms, there may be increased uncertainty in the dose-response curves as they approach the hypothyroxinemia/hypothyroidism threshold, defined herein at the 2.5^{th} percentile of fT4 levels. It is doubtful that TSH expression occurs in an "all or nothing" response immediately at T4 levels below the 2.5^{th} percentile. An

informative analysis would be to add a multiplicative factor to the NIS transport parameters (Vmax and Km for various tissues) that adjusts the effect of NIS inhibition as T4 levels approach the hypothyroid condition. Using this simple approach, the effect of compensatory upregulation of NIS activity can be explored and evaluated as plausible or not. This evaluation may add strength to the model to be used for dose-response assessment for perchlorate exposures up to 20 µg/kg/d, or may suggest that BBDR modeling of perchlorate during pre- and postpartum life stage must include more robust HPT feedback mechanisms to accurately model the effect on the thyroid by perchlorate.

Elizabeth N. Pearce, M.D., M.Sc.

As noted above, I believe that the lack of consideration of the HPT axis in the BBDR model is a very substantial limitation of the model. Effects of NIS inhibition on free T4 cannot necessarily be fully understood without factoring in compensatory processes. In addition, effects of TSH on the T3:T4 ratio might have deleterious effects for fetal hypothyroxinemia which cannot be appreciated without inclusion of the HPT axis in models. I would strongly favor expanding models to include the HPT axis (recognizing that this does add a substantial degree of complexity).

I would also favor eliminating consideration of maternal hypothyroxinemia as a primary outcome for the lactating women. Lactating women would still need to be modeled in order to estimate the amounts of breast milk iodine and perchlorate exposure to inform the model of free T4 in breastfed infants.

I would recommend expanding the pregnancy model to include the first and second trimesters, the gestational ages for which there are currently epidemiologic data to demonstrating adverse developmental effects of maternal hypothyroxinemia.

I would recommend adding effects of concomitant exposures to other environmental NIS inhibitors.

I would expand the literature search and use new data to further validate the expanded models.

Stephen M. Roberts, Ph.D.

The models make a reasonable effort to focus on a range of fT4 levels that is of concern from the standpoint of potential neurodevelopmental effects, yet is not so low as to trigger increased TSH, which would complicate the modeling substantially. The models make a reasonable effort to describe the relationships between iodine intake, perchlorate exposure and thyroid function for the sensitive life stages of interest. The last portion of the charge question appears to be similar to the question posed in 3C, except focuses specifically on the T4 predictions. The response is the same — the robustness, precision, and sensitivity are difficult to gauge based upon the information presented in the report. In part, this is due to the nature of the limited data available for external validation of the model predictions.

Joanne F. Rovet, Ph.D.

I am not sure why HPT feedback control is not considered when TSH is to me a marker of brain sufficiency of thyroid hormone. Thus, I am less than enthusiastic of the quality of the current models for predicting T4 changes following the various perchlorate exposures. Figure 17, however, shows the importance of iodide sufficiency.

V. SPECIFIC OBSERVATIONS ON MODEL REPORT

Hugh A. Barton, Ph.D.

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
12	1-2	Is the wording here, "particularly sensitive" "strongly supported" too strong.
23	15-17	As noted in comments above, clarify this sentence about halting the review process.
24	8	Change "where" to "were"
33	10	Hematocrit is referred to here and several additional times, but the values used do not appear to be reported.
85		In Figures and Tables or report and appendix, some parameters have _SENS added to their names, but it wasn't entirely clear what this meant, e.g., why do some parameters have it and other don't?

Claude Emond, Ph.D.

No specific observations on Model Report provided.

Dale Hattis, Ph.D.

Specific Observations on Model Report

--	--	**List of Abstracts of Papers that May Be Helpful in Quantitatively Estimating the Effects of Iodine and Thyroid Hormone Deficiency on IQ from Exposure During Early Pregnancy** **1. Morreale de Escobar G, Obregón MJ, Escobar del Rey F. Is Neuropsychological Development Related to Maternal Hypothyroidism or to Maternal Hypothyroxinemia? J. Clinical Endocrinology and Metabolism 85: 3975-3987.** **Abstract** Several recent publications have drawn attention to the role of the thyroid hormone status of the mother on the future neuropsychological development of the child. The screening of pregnant women for clinical or subclinical hypothyroidism based on second trimester elevated maternal TSH values has been proposed. **Here, we have summarized present epidemiological and experimental evidence strongly suggesting that conditions resulting in first trimester hypothyroxinemia (a low for gestational age circulating maternal free T_4, whether or not TSH is increased) pose an increased risk for poor neuropsychological development of the fetus.** This would be a consequence of decreased availability of maternal T_4 to the developing brain, its only source of thyroid hormone during the first trimester; T_4 is the

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
		required substrate for the ontogenically regulated generation of T_3 in the amounts needed for optimal development in different brain structures, both temporally and spatially. Normal maternal T_3 concentrations do not seem to prevent the potential damage of a low supply of T_4, although they might prevent an increase in circulating TSH and detection of the hypothyroxinemia if only TSH is measured. Hypothyroxinemia seems to be much more frequent in pregnant women than either clinical or subclinical hypothyroidism and autoimmune thyroid disease, especially in regions where the iodine intake of the pregnant woman is inadequate to meet her increased needs for T_4. It is proposed that the screening of pregnant women for thyroid disorders should include the determination of free T_4 as soon as possible during the first trimester as a major test, because hypothyroxinemia has been related to poor developmental outcome, irrespective of the presence of high titers of thyroid autoantibodies or elevated serum TSH. The frequency with which this may occur is probably 150 times or more that of congenital hypothyroidism, for which successful screening programs have been instituted in many countries. - See more at: [HYPERLINK "http://press.endocrine.org/doi/abs/10.1210/jcem.85.11.6961" \l "sthash.MBJebpGn.dpuf"] **2. Cao XY, Jiang XM, Dou ZH, Rakeman MA, Zhang ML, O'Donnel K, Ma T, Amette K, DeLong N, Delong GR. Timing of vulnerability of the brain to iodine deficiency in endemic cretinism. N Engl J Med. 1994 Dec 29;331(26):1739-44.** **Abstract** **BACKGROUND:** Endemic cretinism, caused by severe iodine deficiency during pregnancy, is the world's most common preventable cause of mental retardation. It can be prevented by iodine treatment before conception, but whether it can be prevented or ameliorated by treatment during pregnancy or after delivery is not known. **METHODS:** In a severely iodine-deficient area of the Xinjiang region of China, we systematically administered iodine to groups of children from birth to three years of age (n = 689) and women at each trimester of pregnancy (n = 295); we then followed the treated children and the babies born to the treated women for two years. We used three independent measures of neural development: the results of the neurologic examination, the head circumference (which correlates with brain weight in the first postnatal year), and indexes of cognitive and motor development. Untreated children one to three years of age, who were studied when first seen, served as control subjects.

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
		RESULTS: The prevalence of moderate or severe neurologic abnormalities among the 120 infants whose mothers received iodine in the first or second trimester was 2 percent, as compared with 9 percent among the 752 infants who received iodine during the third trimester (through the treatment of their mothers) or after birth (P = 0.008). The prevalence of microcephaly (defined as a head circumference more than 3 SD below U.S. norms) decreased from 27 percent in the untreated children to 11 percent in the treated children (P = 0.006), and the mean (+/- SD) developmental quotient at two years of age increased (90 +/- 14, vs. 75 +/- 18 in the untreated children; P < 0.001). Treatment in the third trimester of pregnancy or after delivery did not improve neurologic status, but head growth and developmental quotients improved slightly. Treatment during the first trimester, which was technically problematic, improved the neurologic outcome. **CONCLUSIONS:** Up to the end of the second trimester, iodine treatment protects the fetal brain from the effects of iodine deficiency. Treatment later in pregnancy or after delivery may improve brain growth and developmental achievement slightly, but it does not improve neurologic status. **Comment in** [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/7984200"] [N Engl J Med. 1994] 3. **Gilbert M, Rovet J, Chen Z, Koibuchi N.** [HYPERLINK "http://www.sciencedirect.com/science/article/pii/S0161813X11002051"], **Neurotoxicology, Volume 33 (2012) 842-852.** **Abstract** Thyroid hormones (TH) are critical for growth and development and particularly brain development. There are numerous environmental agents that lead to marginal reductions of circulating TH. Although it is clear that severe developmental hypothyroidism is profoundly detrimental to neurodevelopment, there is less information regarding the consequences of modest degrees of thyroid. The impact of low level TH disruptions induced by environmental contaminants has not been defined. This paper is a synopsis from four invited speakers who presented at the 13th International Neurotoxicology Association meeting held in Xi'an, China during the summer of 2011. An overview of the role of TH in brain development and a review of human and animal data on the neurological sequelae of disruption of the thyroid axis in the pre- and early post-natal periods were presented by Mary Gilbert and Joanne Rovet. Iodine deficiency, a common cause of TH

Specific Observations on Model Report

		insufficiency and mental retardation in many countries, including China, was addressed by Zupei Chen. In this presentation the current incidence of iodine deficiency and neurological outcome in China and the efficacy of recently implemented iodinization programs to eliminate this cause of mental retardation were reviewed. Joanne Rovet described the impact of TH disruption during pregnancy and under conditions of congenital hypothyroidism. Children born with normal thyroid function, but who experienced TH insufficiency in the womb, display subtle cognitive impairments and abnormalities in brain imaging. Despite early detection and treatment, deficiencies also exist in children born with thyroid disorders. Different patterns of cognitive effects result from prenatal versus postnatal TH insufficiency. Mary Gilbert reported on the effects of environmental contaminants with thyroid disrupting action on brain development in animals. Results of neurophysiological, behavioral, structural and molecular alterations that accompany modest perturbations of the thyroid axis were reviewed. Noriyuki Koibuchi described molecular targets of TH-mediated signaling accompanying exposure to persistent organic pollutants. Both polychlorinated biphenyls (PCBs) and polybrominated diphenyl ethers (PBDEs) are prevalent environmental contaminants that disrupt TH signaling at the receptor level. This action by these chemical classes could contribute to the negative impact of these chemicals on brain function. In summary, epidemiological, preclinical and animal research has clearly identified the critical role of TH in brain development. Additional work is required to understand the impact of low level perturbations of the thyroid axis to evaluate the risk associated with environmental contaminants with thyroid action. 4. 		(TSH) concentrations less than the newborn screening cutoffs. We assessed the association between neonatal TSH concentrations and educational and developmental outcomes. **Methods** We did a population-based record-linkage study of all liveborn infants undergoing newborn screening from 1994 to 2008 in New South Wales, Australia, with assessments of childhood development or school performance. Very-low-birthweight babies (<1500 g) were excluded. Developmental and educational outcomes were obtained and these were linked to individual records by the New South Wales Centre for Health Record Linkage. The primary educational outcome was the proportion of students with National Assessment Program Literacy and Numeracy (NAPLAN) results lower than the national minimum standard in reading or numeracy measured at all ages, and the primary developmental outcome was the proportion of children who were classified as being developmentally high risk (vulnerable in two or more of the five developmental domains assessed by the Australian Early Development Census) at age 4–6 years. The proportions of infants with each outcome were calculated per percentile (0–100) of TSH concentration. Multivariable logistic regression was used to account for potential confounding by maternal and fetal variables known to affect neonatal TSH concentrations or neurodevelopmental outcomes. **Findings** 503 706 infants had a neonatal TSH result that linked to a developmental or educational outcome. 149 569 infants born between 2002 and 2008 were linked to an Australian Early Development Census developmental outcome and 354 137 were linked to a NAPLAN educational outcome. Median follow-up for educational outcome was 10 years (IQR 8–12) and for developmental outcome was 5 years (5–6). 5·5% (14 137 of 257 752) of infants with TSH concentrations lower than the 75th percentile scored less than the national minimum standard for numeracy, and this increased with each increase of percentile group to 11·3% (15 of 133) of infants with a TSH concentration between the 99·90th and 99·95th percentile. Infants with a neonatal TSH concentration in the 99·95th percentile or higher (above newborn screening cutoff) and likely to have diagnosed and treated congenital hypothyroidism had similar results to infants with a TSH concentration lower than the 75th percentile for both educational and developmental outcomes. Infants with a neonatal TSH concentration between the 99·5th and 99·9th percentile were more likely to have special needs (adjusted odds ratio [aOR] 1·68, 95% CI 1·23–2·30), poor numeracy performance (aOR 1·57, 1·29–1·90), and developmentally high risk (aOR 1·52, 1·20–1·93).

		Interpretation We found an association between neonatal TSH concentrations lower than the present newborn screening thresholds and poor educational and developmental outcomes. This association needs further investigation to assess whether assessment and treatment of these infants might improve their long-term cognitive outcomes. **Funding** Australian National Health and Medical Research Council. 6. **Bath SC, Steer CD, Golding J, Emmett P, Rayman MP. Effect of inadequate iodine status in UK pregnant women on cognitive outcomes in their children: results from the Avon Longitudinal Study of Parents and Children (ALSPAC), Lancet. 2013 Jul 27;382(9889):331-7. doi: 10.1016/S0140-6736(13)60436-5. Epub 2013 May 22.** **Summary** **Background: As a component of thyroid hormones, iodine is essential for fetal brain development. Although the UK has long been considered iodine replete, increasing evidence suggests that it might now be mildly iodine deficient. We assessed whether mild iodine deficiency during early pregnancy was associated with an adverse effect on child cognitive development.** **Methods: We analysed mother–child pairs from the Avon Longitudinal Study of Parents and Children (ALSPAC) cohort by measuring urinary iodine concentration (and creatinine to correct for urine volume) in stored samples from 1040 first-trimester pregnant women. We selected women on the basis of a singleton pregnancy and availability of both a urine sample from the first trimester (defined as ≤13 weeks' gestation; median 10 weeks [IQR 9–12]) and a measure of intelligence quotient (IQ) in the offspring at age 8 years. Women's results for iodine-to-creatinine ratio were dichotomised to less than 150 µg/g or 150 µg/g or more on the basis of WHO criteria for iodine deficiency or sufficiency in pregnancy. We assessed the association between maternal iodine status and child IQ at age 8 years and reading ability at age 9 years. We included 21 socioeconomic, parental, and child factors as confounders.** **Findings: The group was classified as having mild-to-moderate iodine deficiency on the basis of a median urinary iodine concentration of 91·1 µg/L (IQR 53·8–143; iodine-to-creatinine ratio 110 µg/g, IQR 74–170). After adjustment for confounders, children of women with an iodine-to-creatinine ratio of less than 150 µg/g were more likely to have scores in**

		the lowest quartile for verbal IQ (odds ratio 1·58, 95% CI 1·09–2·30; p=0·02), reading accuracy (1·69, 1·15–2·49; p=0·007), and reading comprehension (1·54, 1·06–2·23; p=0·02) than were those of mothers with ratios of 150 µg/g or more. When the less than 150 µg/g group was subdivided, scores worsened ongoing from 150 µg/g or more, to 50–150 µg/g, to less than 50 µg/g. **Interpretation: Our results show the importance of adequate iodine status during early gestation and emphasize the risk that iodine deficiency can pose to the developing infant, even in a country classified as only mildly iodine deficient. Iodine deficiency in pregnant women in the UK should be treated as an important public health issue that needs attention.** **7. Min H, Dong J, Wang Y. et al. Maternal Hypothyroxinemia-Induced Neurodevelopmental Impairments in the Progeny. Molecular Neurobiology 53(3): 1613-1624.** **Abstract** Maternal hypothyroxinemia can induce neurodevelopmental impairments in the developing fetus. We here review recent studies on the epidemiology and molecular mechanisms associated with this important public health issue. In 2011, the American Thyroid Association defined maternal hypothyroxinemia as low serum free thyroxine (FT4) levels (<5th or <10th percentile) existing in conjunction with normal serum free triiodothyronine (FT3) or thyroid stimulating hormone (TSH) levels during pregnancy. Compared to clinical or subclinical hypothyroidism, hypothyroxinemia is more commonly found in pregnant women. Hypothyroxinemia usually ensues in response to several factors, such as mild iodine deficiency, environmental endocrine disrupters, or certain thyroid diseases. Unequivocal evidence demonstrates that maternal hypothyroxinemia leads to negative effects on fetal brain development, increasing the risks for cognitive deficits and poor psychomotor development in resulting progeny. In support of this, rodent models provide direct evidence of neurodevelopmental damage induced by maternal hypothyroxinemia, including dendritic and axonal growth limitation, neural abnormal location, and synaptic function alteration. The neurodevelopmental impairments induced by hypothyroxinemia suggest an independent role of T4. Increasing evidence indicates that adequate thyroxine is required for the mothers in order to protect against the abnormal brain development in their progeny. **8. 		early pregnancy with off spring IQ and brain morphology in childhood: a population-based prospective cohort study. The Lancet Diabetes-Endocrinology 2016 4:35-43. **Background** Thyroid hormone is involved in the regulation of early brain development. Since the fetal thyroid gland is not fully functional until week 18–20 of pregnancy, neuronal migration and other crucial early stages of intrauterine brain development largely depend on the supply of maternal thyroid hormone. Current clinical practice mostly focuses on preventing the negative consequences of low thyroid hormone concentrations, but data from animal studies have shown that both low and high concentrations of thyroid hormone have negative effects on offspring brain development. We aimed to investigate the association of maternal thyroid function with child intelligence quotient (IQ) and brain morphology. **Methods** In this population-based prospective cohort study, embedded within the Generation R Study (Rotterdam, Netherlands), we investigated the association of maternal thyroid function with child IQ (assessed by non-verbal intelligence tests) and brain morphology (assessed on brain MRI scans). Eligible women were those living in the study area at their delivery date, which had to be between April 1, 2002, and Jan 1, 2006. For this study, women with available serum samples who presented in early pregnancy (<18 weeks) were included. Data for maternal thyroid-stimulating hormone, free thyroxine, thyroid peroxidase antibodies (at weeks 9–18 of pregnancy), and child IQ (assessed at a median of 6·0 years of age [95% range 5·6–7·9 years]) or brain MRI scans (done at a median of 8·0 years of age [6·2–10·0]) were obtained. Analyses were adjusted for potential confounders including concentrations of human chorionic gonadotropin and child thyroid-stimulating hormone and free thyroxine. **Findings** Data for child IQ were available for 3839 mother–child pairs, and MRI scans were available from 646 children. Maternal free thyroxine concentrations showed an inverted U-shaped association with child IQ (p=0·0044), child grey matter volume (p=0·0062), and cortex volume (p=0·0011). For both low and high maternal free thyroxine concentrations, this association corresponded to a 1·4–3·8 points reduction in mean child IQ. Maternal thyroid stimulating hormone was not associated with child IQ or brain morphology. All associations remained similar after the exclusion of women with overt hypothyroidism and overt hyperthyroidism, and after adjustment for concentrations of human chorionic gonadotropin, child thyroid-

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
		stimulating hormone and free thyroxine or thyroid peroxidase antibodies (continuous or positivity). **Interpretation** Both low and high maternal free thyroxine concentrations during pregnancy were associated with lower child IQ and lower grey matter and cortex volume. The association between high maternal free thyroxine and low child IQ suggests that levothyroxine therapy during pregnancy, which is often initiated in women with subclinical hypothyroidism during pregnancy, might carry the potential risk of adverse child neurodevelopment outcomes when the aim of treatment is to achieve high-normal thyroid function test results. **9.** [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Taylor%20PN%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Okosieme%20OE%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Murphy%20R%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Hales%20C%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Chiusano%20E%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Maina%20A%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Joomun%20M%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Bestwick%20JP%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Smyth%20P%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Paradice%20R%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Channon%20S%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Braverman%20LE%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Dayan%20CM%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK "https://www.ncbi.nlm.nih.gov/pubmed/?term=Lazarus%20JH%5BAuthor%5D&cauthor=true&cauthor_uid=25057878"], [HYPERLINK

6	5-16	This risks missing possibly the most serious effects on IQ for pregnant women in the lowest range of iodide intake. This may not control RfD selection, but may well be very important for estimating overall IQ effects

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
		and therefore juxtaposing costs and benefits of alternative choices of RfDs and measures to reduce perchlorate exposures.
6	18-21	Could be a substantial limitation.
7	2-8	Critically evaluate this evidence supporting model calibration.
7	9-16	These ranges of iodide intake seem unduly restricted—support with reference to actual US iodide intake and excretion information from NHANES.
7	17-25	Having "reference intervals" as the touchstone of the analysis is distinctly suboptimal for juxtaposing relative costs and benefits of regulatory options. Much better would be to make predictions of IQ effects which can be economically valued and juxtaposed with estimates of economic costs.
7	26-32 33-36 Footnote 2	What? No analysis of variability and uncertainty in this parameter (refers to "the revised value" implying no distributional treatment for what is stated to be a key component of the analysis). Variability—why is it assumed that everyone is the same in this? Uncertainty—surely the value has not been determined to a precision where the implications of uncertainty need not be analyzed.
8	15-20	Analysis by "reference range" is likely to be misguided. Changes within the reference range may still be associated with harm. This focus on reference ranges and the lack of data for potentially the most vulnerable segment of the population is an additional reason to treat the modeling results with considerable caution in judging appropriate exposure control standards.
9	6-13	This clearly requires quantitative assessment of the effects of exposure changes for the entire population, not just the segments for which a "reference range" is available. The effects of interest include prominently those on IQ, for which it would be possible to juxtapose quantifiable economic benefits with quantifiable economic costs. And the analysis must clearly include the full range of iodine intakes in the real US population, as best it can be estimated from available data.

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
11	1-13	These references must be systematically evaluated in order to convert the analysis to implications for IQ changes rather than just "hypothyroxemia." Such conversion is essential for a reasonable juxtaposition of costs and benefits of regulatory alternatives. The abstract for the most recent Min et al. Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
		brain size measures. This would allow reframing of measures of TH perturbation to measures of IQ directly relatable to serious economic and other consequences as a function of iodide intake distributions.
14	--	Model should clearly be extended to cover effects during early pregnancy where T4 deficiency is likely to have the greatest effects on neurodevelopment.
16	footnote	[3] Here we use "reference range" to refer to the range of a hormone that is considered normal and healthy for a population. Hence some in the population will have hormone levels above or below that reference range and be identified as having an adverse clinical condition. The "population distribution" refers to the distribution of hormone levels in the entire population, including those outside of the reference range. [4] The model does not describe TSH levels, but assumes they stay within the normal reference range. Clinically, significant elevations in TSH can be observed whether or not T4 of fT4 are in the reference range. Thus there are not specific levels of T4/fT4 that are definitively associated with TSH elevation. This may be due to inter-individual variability in hormonal control mechanisms. But mechanistically it is known that TSH production and release are stimulated by decreasing T4 levels. Hence for the purpose of this model, specific, life-stage-specific fT4 levels are identified below which TSH levels are expected to be sufficiently stimulated as to rise above their reference range and introduce significant feedback control on the thyroid, which would make model predictions invalid.
17	12-21	There is no apparent justification for drawing the line at the 2.5th percentile. This is pretty important because it may be that later the authors essentially ignore possible effects outside this limit, thus potentially biasing the analysis by excluding an especially sensitive segment of the population.
17	22-24	I think this is a problem for the analysis—levels of iodide intake below this are present in the US population (analyze NHANES data) and likely represent a sensitive subgroup that could affect expected IQ benefits of perchlorate exposure reduction.
18	2-13	
18	14-25	There is a grave danger here of understating perchlorate hazard and benefits of exposure reduction. The analysis should consider the effects of perchlorate for the full range and frequency of iodide exposures in the U.S. population. Otherwise both the baseline amount of harm from current perchlorate exposures and the benefits and costs of changes in those exposures will be mis-analyzed. (give fuller analysis of this distribution here?)
20	8-15	More explanation is needed for the choice of this distribution. Why not use a lognormal? Data should be shown to indicate that a normal or lognormal does not fit, if that is true. See analysis of the data in App-25 below.
44	22-24	

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
45	1-23	The single-value for this binding constant has been changed more than 2-fold from the earlier value. Yet there is no allowance for either variability or uncertainty. This should be improved in subsequent analyses to at least provide some sensitivity analysis for both uncertainty and variability. Analyze in detail.
45	9-16	Overall this conclusory presentation leaves much to be desired. Comparisons to the data fits before and after revision should be provided to allow a meaningful review.
45	17-23	This certainly suggests that something may be amiss in the basic calibration of the model. It is reassuring that the author does not think that key predictions in the current analysis are not affected much, but because other uses of the model are expected in the future, this issue may well need to be revisited.
46	2-12	
60	10-19	This is completely unconvincing. The figure referred to has an enormous amount of scatter, even with the data points plotted on a logarithmic y-axis. To then say, given this scatter, that "the model-predicted urinary iodide concentrations…were within the range of literature-reported values (Figure 4) really is such a loose standard that it seems hardly meaningful. Minimally, there needs to be some statistical summarization of the comparison data and some specific comparison of the summary data with a specific set of model predictions.
61	6-12	The comparison depicted in the bottom panel is also unconvincing, lacking any statistical summarization to help the reader judge whether the comparison supports or refutes the predictions of the model.
63	10-17	Similarly, the conclusion from Figure 6 that the predicted perchlorate concentrations are "within the range of reported values" is completely unconvincing. What is shown in Figure 6 is a plot of highly scattered observations plotted over a four order of magnitude range with no statistical summarization of the data to allow reasonable juxtaposition of the central tendency and uncertainty range of the observations with corresponding model expectations.
64	9-13	The lack of correspondence of the data points to model predictions is unsettling. And the proffered explanation "that iodide levels are not stable in breast-milk samples" is no help. Instability would be expected to lead to scatter of the data points, but not a systematic bias lowering the data points relative to model expectations. The modelers' response in this case makes no sense.
67	11-12	As indicated by my remarks above, I disagree. The authors should develop a range of alternative models that would fit these data as well or better based on much more rigorous criteria than that the models produce results "within the range" of the observations presented on multi-order-of magnitude plots. They should then document the implications of the alternative models for the

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
		effect of various levels of perchlorate on range of policy-relevant parameter values such as IQ distributions.
69	7-12	Although the authors seem to be following SAB advice in this choice of criteria for defining adversity, I think it would be much better to use-IQ change criteria based on recently available information. Making IQ change the focus of the analysis can build upon the modeling work done so far, but yield results in terms that can be valued economically and juxtaposed much more readily with costs of alternative measures to reduce perchlorate exposures. This corresponds much more closely to the mandate for analysis under the Safe Drinking Water Act, as I understand it and described in the introductory sections of the model report.
70	11-14	There should be an analysis of the effects of a plausible uncertainty range for this parameter, given that it has been appreciably changed from what was assumed in prior modeling. The authors may also wish to explore the potential consequences of variability among people in the values of this key parameter, particularly if a literature search yields evidence of a polymorphism in the gene related to this binding constant. At the very least, there should be some discussion of the possibility that this gene may be polymorphic.
71	3-6	Surely the model results are uncertain both above and below the indicated level. Perhaps they are more uncertain below 10.6 ppm but the criterion indicated cannot indicate a sharp cutoff where uncertainty starts.

Angela M. Leung, M.D., M.Sc.

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
Throug hout	--	Suggest replacing the term "bottle-fed" with "formula-fed" throughout the report and its figures. Currently, both are used interchangeably, and thus it should be clarified that the contents of the infant bottle are referring to only infant formula, rather than breastmilk or a combination of both.
8	10	Suggest deleting "medically"
16	Footnote 4	• Suggest clarifying the first sentence by inserting "serum" before TSH. • The second sentence would be better rephrased by deleting the word "Clinically". • There is typo in the second sentence: "T4 or FT4" levels The 4th and 5th sentences should be combined and can be better rephrased as: "This may be due to inter-individual variability in hormonal control mechanisms, but TSH is generally stimulated by decreasing T4 levels."
16	4	The word "both" here may be confusing with this sentence structure –

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
		consider deleting.
16	8	The HPT axis should be assumed to be intact in all individuals, which this sentence suggests again. Recommend replacing the phrase "involved with regulating thyroid hormone concentrations" with "perturbed".
16	14	Recommend deleting "just"
17	3	Should be "conditions"
17	8	Suggest replacing "Elevated TSH levels" with "Elevated serum TSH concentrations"
17	13-14	Suggest replacing "euthyroid conditions occur for" with "euthyroidism is defined as", and "hypothyroxinemia occurs for" with "hypothyroxinemia is defined as"
17	20-21	Typos in this sentence with the missing end parentheses and double period.
18	19	Note that the recommended iodine intake for lactating women of 250 mcg/day is that by the WHO, UNICEF, and ICCIDD (now IGN), but the U.S. Institute of Medicine has a slightly different recommendation of 290 mcg/day for lactating women.
20	1	Insert: "For the formula-fed infant, the age-specific mean fT4 concentration was defined…"
21	Table 1	• The units of FT4 should be included. • It should be clarified that these are serum FT4 concentrations. It is customary to use the term "full-term" rather than "normal-term" infants.
32	Figure 3	The arrow terminating in "infant ingestion" may be misleading to some and can be better redrawn to clarify that this is not resulting in the set of processes immediately below this (i.e. thyroid plasma refers to the mother, not the infant).
37	6	It can also be cited that the placenta strongly expresses the type III deiodinase (Roti et al; PMID 7263836), thus partially responsible for the high rT3 levels seen at birth.
61	3	Typo: Should be cow milk-based formula
61	6-12	Suggest use of the term "urinary perchlorate concentrations" throughout this paragraph to minimize potential confusion
80	14	The subscript #11 appears to be a typo and can be deleted

Michael H. Lumpkin, Ph.D., DABT

No specific observations on Model Report provided.

Elizabeth N. Pearce, M.D., M.Sc.

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
6	20	"thyroid hormone excretion" would be better worded as "thyroid hormone synthesis and secretion"
16	Footnote 4	"mechanistically it is known that TSH production and release are stimulated by decreasing T4 levels": it is primarily decreased T3 (converted locally from T4 by type 2 deiodinase), that provides feedback at the pituitary and hypothalamus
18	1-3	"The pregnancy model was primarily developed and calibrated using an assumed iodine intake of 200 mcg/d, the level recommended for pregnant women": The Institute of Medicine's RDA for pregnancy is 220 mcg daily. The WHO recommends 250 mcg (WHO Secretariat, Andersson M, de Benoist B, Delange F, Zupan J. Prevention and control of iodine deficiency in pregnant and lactating women and in children less than 2-years-old: conclusions and recommendations of the Technical Consultation. Public Health Nutr. 2007;10(12A):1606-11).
18	19-20	"The lactating mother model was primarily calibrated or tuned assuming iodine ingestion of 250 mcg/d, the level recommended for breast-feeding women.": The Institute of Medicine's RDA for lactation is 290 mcg daily. WHO recommends 250 mcg.
33	12	It is noted that infant plasma volume was calculated based on a study with an n of only 4. Are there more robust data available?
47	Table 6	It is unclear to me why the estimated body weight for lactating women would start out higher (74.6 kg) than that for women in the late third trimester of pregnancy (72.3 kg).
64 and 82		It is noted, per a personal communication from Ben Blount that iodine levels decrease with storage time of breast milk samples. This simply does not make sense if measurement techniques are adequate. There could be some degradation of matrices which might affect iodine measurements by some methods, but the iodine can't actually leave the sample.

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
1		Title is not accurate re "pregnant mother and fetus"
6	20-21	This assumption is not clear to me and I don't agree with it
7	13-14	This was confusing to me
7	27	Grammar – "which" describing wrong referent
8	1-3	Where is the evidence for this?
8	4-5	Where is the evidence for this?
8	15-18	What is the relevance of this statement
8	19	Wouldn't data from preterm cohorts suffice here?
11	15	Add "respectively" after "(hypothyroxinemia)"
12	1-2	I think this conclusion is out of context; it was meant infants versus grown men
12	5-7	I disagree – the real reason for suggesting greater sensitivity of infants than older children was the knowledge that the developing brain had a greater need for thyroid hormone at this earlier age
13	7	Why lactating mothers?
13	23	7-90 days is not the *most sensitive* period of thyroid function maturation; clearly gestational thyroid-hormone deficiency also has a major impact, particularly on behavior and vulnerability to later mental health issues
17	15	I am not happy with defining hypothryxinemia for fT4 from 2.5-10th percentiles; Most studies are at least below 5th percentile. This is a statistical decision for studying effects, not a clinical condition
19	21-22	I don't understand this
20	8-11	Too technical
20	16-22	Please cite proper evidence
21	4	Remove "for example" - repeated
42	14	Add "in" before "umen"
43	4-5	Where does this idea come from – not sure it is true
43	5-6	Why? Where?
43	8-9	Why?
43	14	Comma after T3
43	14-15	Why?
44	5-6	Remove brackets around "McLanahan
44	6	"(see also U.S. EPA, 2009)
60	2	Perhaps cite Figure numbers in brackets
60	9	On what basis? Too vague.
60	16-22	Long sentence, hard to read
66	10-13	Confusing
67	11	Vague – what do you mean by "considered adequate"
70	11-13	Also Figure 10: where do these data come from?

Specific Observations on Model Report		
Page	***Line***	***Comment or Question***
77		Figure 14 Right – what is meant by "maternal iodine: 75 µg/d)"? Is this relevant?
78	8	Comma after "100 µg/L"
78	7-10	Long sentence, difficult to follow; not sure how you draw conclusion in sentence – where is the data
79	15	Where do reference values for fT4 come from
80	5-6	Not clear
80	14	"11": Actually, the Vulsma paper predict ~40%
80	11-13	Where are the data in Leung et al 2012? Did she provide the authors with the raw data as they only report correlational results?
83	11	Replace "birth" with "day 7"
84	1-3	Where are these data?

VI. SPECIFIC OBSERVATIONS ON MODEL APPENDICES

Specific Observations on Model Appendices		
Page	***Line***	***Comment or Question***
App-11	7-10	The fit in figure B-5 is clearly improved over the one that simply went through the lowest point. However the fit should be by inverse-variance weighted least squares not informal choose a value and evaluate fit by eye.
App-12	40-42	Why not assume an actual estimate of either national average or local perchlorate water and food exposures in the area where Greer et al. drew their subjects?
App-24 and -25		There is no specific analysis of the assembled data to evaluate the fit of simpler normal or lognormal distributions to the different observations and justify the use of the more complex lambda sigma model, which has one more parameter than a lognormal. I generated the following for simple normal and lognormal distributions for selected data sets with the most complete descriptions of the information. Overall, lognormal distributions seem to provide adequate fits, and although normal distributions provide a marginally better fit in a few specific cases, there is one case (Wang et al. first trimester) where the normal distribution falls conspicuously short in the fit as measured by the R squared statistic. I doubt that an Akaike information criterion test would find that the extra parameter needed for the lambda sigma distribution model would be justified.

Specific Observations on Model Appendices		
Page	***Line***	***Comment or Question***
App-17	7-10	"Also, the lactating mother has the demands of lactation, which clears iodide and T4 from her system. The mother's basal levels of fT4... are seen to decline 23% from postnatal day 7 to 90, which may be in part because the rate of milk ingestion, hence clearance of iodide and T4, is increasing": lactation does clear significant iodine from the system, but only a very trivial amount of thyroid hormone is secreted into breast milk, certainly not enough to contribute substantially to a decrease in maternal FT4.
App-17	21-22 and 30	It is noted in lines 21-22 that maternal fT4 stabilizes after 2-3 weeks postpartum (which makes sense, given that the half-life of TBG is about 5 days and that of T4 is about 8 days), but this seems to be partially contradicted by the statement in line 30 that maternal serum fT4 decreases with time. Line 30 refers to the right panel of Figure D-4, but I think it should be the right panel of figure C-1.
App-25	Table E-1	As noted above, it would be helpful to provide more information about study cohorts here, particularly with respect to exclusion of TPO and/or thyroglobulin antibody positive women and the population iodine status
App-34	9-10	With respect to pregnant women, "The amount of free iodide in the thyroid was assumed to be a very small quantity, negligible compared to the flux in and out": This is not consistent with the knowledge that the average adult thyroid in iodine-sufficient regions contains 10-20 mg of iodine (accounted for by the CTGIPOOL variables in the infants and lactating mothers).
App-36	18-22	It is noted that in infants if T4 production declines there will be a compensatory increase in the relative rate of T3 production. This is appropriate. However, it is stated that "This mechanism is not assumed to apply in the mother": It is unclear why this is not assumed in the mother, particularly because increases in the maternal ratio of T3:T4 in pregnancy produced could have deleterious effects on the fetus.

Subject: Update on Perchlorate BBDR Model Revisions and MCLG Approach

Perchlorate Workgroup Members,

As we discussed at our last workgroup meeting, please find attached for your information an update on revisions to the perchlorate BBDR model and MCLG approach. The revisions are based on panel member recommendations discussed at the peer review meeting (we have not received the draft panel report).

Thanks,

Dan

Expansion of BBDR model and MCLG Approach to Early Pregnancy
February 15, 2017 Update

Draft Peer Review Report

- Versar recently provided EPA with the Draft Peer Review Report for review
- BBDR model team is reviewing, initial/cursory review -
    - Report confirms the direction of the work underway to model early pregnancy and conduct additional uncertainty analysis
    - Report also states that, "a model is never done" and recommends that at some point EPA use the model as-is and make additional refinements in the future. Examples provided include co-exposure to other goitrogens, compensatory effects in response to perchlorate inhibition and probabilistic inputs.
    - If necessary, EPA reviewers may send 2-3 clarifying questions back to Versar before finalizing the report.
- Moving forward, the BBDR model team has agreed to:
    - Continue modeling early pregnancy
    - Qualitatively discuss other goitrogens rather than quantitatively featuring them as part of the BBDR model
    - Continue investigating how to address TSH feedback with regard to Human Chorionic Gonadotropin (hCG) feedback *in utero*
    - Seek input from ORD thyroid experts

Model extrapolation to early pregnancy – *continuation of work*

- Dr. Schlosser (EPA/ORD/NCEA) is editing primary model code
- Dr. Leavens (ORNL contractor) working on growth equations
- Initial early pregnancy data obtained from contractor
- Next steps: Abt to provide T4, fT4, T3 data for non-pregnant woman (childbearing age) as a function of time in/through first trimester

Uncertainty analysis

- Dr. Kapraun (EPA/ORD/NCEA) has version of model code and statistical model for Bayesian analysis prepared, successful test with simulated data
- Next steps: Dr. Gay Goodman has transmitted Greer study data to EPA (both radio-iodide uptake and perchlorate blood and urinary data expected). Further discussions are warranted.

Continued evaluation of other goitrogens and data on fT4-TSH relationship in NHANES data (2011-2012)

MCLG approach

- The Approach report is being updated to include the additional studies found in the updated literature search.
- The Korevaar data is being analyzed. Clarification questions on the organization of the data sets have been asked of Korevaar in order to reproduce his analysis and then derive a continuous dose response function.
- An outline of a revised MCLG Approach report to accommodate an expanded BBDR model has been drafted and reviewed by Abt.
- Additional thyroid hormone data has been compiled per Dr. Schlosser's request. A teleconference with Dr. Schlosser will take place this week to transfer the information and identify additional data.

Deadline - due to Ann by COB tomorrow

Would you please have your staff do a quick review of the fact sheets for our priority contaminants (e.g., contaminants on CCL, reg det lists)? Please note the fact sheets for PFOA, PFOS, perchlorate are on hold.

I am reading the request from my iphone so I haven't opened all the files...1,4-dioxane, ndma, Rdx are a few of the ones i've opened thus far.

Subject: FOR YOUR REVIEW: FFRRO Technical Fact Sheets Update

Folks, I'm hoping this is an easy lift. OLEM has provided the attached technical fact sheets for one last round of review prior to seeking OPA approval to post. My sense is to the extent they impact us, you all have been engaged already. Please let me know if you have any comments on the attached. Note that the PFOA?PFOS and Perchlorate factsheets have been put on hold so they are not part of this package.

Lee has asked for our review with all deliberate speed. If you could give me a sense of where you're at in your review by COB tomorrow, I'd greatly appreciate it.

If you have any questions, please let me know!
Ann

Washington, D.C. 20005

Re: NRDC-Observations on Tolerances for Hypochlorite to Minimize Degeneration to Perchlorate, Correspondence Dated July 31, 2014

Dear Mr. Neltner and Ms. Maffini:

Thank you for your July 31, 2014 correspondence presenting NRDC's "observations on tolerances for hypochlorite to minimize degeneration to perchlorate." The letter requests that, during the registration review for sodium and calcium hypochlorite (Na and Ca hypochlorite), the Environmental Protection Agency (EPA) consider setting tolerances for sodium and calcium hypochlorite to limit perchlorate residues. In addition, NRDC suggests that EPA should use the Na and Ca hypochlorite registration review to determine, pursuant to 21 USC § 346a(a)(3), that perchlorate is a degradation product of hypochlorite and is "likely to pose a potential health risk from dietary exposure in food and water that is of a different type than and of a greater significance than the risk posed by dietary exposure to hypochlorite." NRDC recommends that the agency, in assessing the risk of hypochlorite use in food processing, take into consideration the combined effect of perchlorate, thiocyanate, and nitrate on fetuses and infants and aggregate exposure to perchlorate from all sources including hypochlorite and plastic packaging. The letter additionally suggests that hypochlorite pesticide products should have an expiration date to further minimize perchlorate levels. While the letter falls outside of any currently open registration review comment period for Na and Ca hypochlorite, we will post your comments to the docket[1] along with this response.

EPA agrees with the observation in your letter that research by the American Water Works Association and the Water Research Foundation suggest the potential for perchlorate to form in stored hypochlorite solutions.[2] As noted in the research, the American Water Works Association

[1] Registration review of Na and Ca hypochlorite; Docket ID # EPA-HQ-OPP-2012-0004 at www.regulations.gov
[2] Stanford, B.D., A. Pisarenko, S. Snyder, and G. Gordon, Perchlorate, Bromate, and Chlorate in Hypochlorite Solutions: Guidelines for Utilities. Journal - American Water Works Association, 2011. 103(6): p. 71-83. Available at http://www.awwa.org/publications/journal-awwa/abstract/articleid/28067.aspx. And: Stanford, B.D., A.N. Pisarenko, S.A. Snyder, and G. Gordon, Minimizing Perchlorate Formation in Hypochlorite Solutions, Opflow, 2009. 35(10): p. 10-13. http://www.waterrf.org/ExecutiveSummaryLibrary/4147_NON_profile.pdf.

and the Water Research Foundation found hypochlorite concentration, pH, ionic strength, and temperature were major factors impacting perchlorate formation in stored hypochlorite solutions at drinking water utilities.[3] Additionally, recent monitoring data included in the EPA Office of Water's Unregulated Contaminant Monitoring Rule (UCMR 3) found increased levels of chlorate in finished drinking water.[4] Therefore, the agency intends, as part of its next steps in the registration review of Na and Ca hypochlorite, to take an in-depth look at the requests in your letter, including whether any action is appropriate under the FFDCA, and to consider, among other things, possible labeling language to optimize storage of hypochlorite products in order to minimize perchlorate and chlorate formation during storage.

As you know, the EPA Office of Water has begun the National Primary Drinking Water Regulation (NPDWR) process for perchlorate. To inform this effort, EPA and Food and Drug Administration scientists developed a Biologically Based Dose Response (also known as a Physiologically-Based Pharmacokinetic (PBPK)) model to inform the agency's SDWA decision making. In light of this, the Office of Pesticide Programs (OPP) will continue to work with the Office of Water on perchlorate issues during registration review for Na and Ca hypochlorite.

Thank you for your interest and input into the registration review of Na and Ca hypochlorite. We continue to welcome any information that you have or become aware of in the future that relates to this issue and the Na and Ca hypochlorite registration review. If you have any questions concerning this response, please contact Rose Kyprianou at (703) 305-5354 or Kyprianou.Rose@epa.gov.

Sincerely,

Steve Knizner
Director
Antimicrobials Division
Office of Pesticide Programs
U.S. Environmental Protection Agency

Subject: FW: Letter to Administrator McCarthy re: Perchlorate Rulemaking
Attachments: psg - bbdr policy letter to admin mccarthy 11.29.16.pdf; ATT00001.htm

Lisa,

In the attached letter the PSG raises a number of concerns including the CD. Their recommendations follow:

- The peer review panel **should** draft the report not Versar;
- Comments **should** be provided to the panel, not a summary;
- Panel recommendations **should** be a consensus not individual perspectives; and
- EPA **should** update occurrence information prior to drafting the HRRCA because:
  - 30% of the UCMR 1 samples were collected at entry points,
  - There has been significant declines in perchlorate occurrence since 2001-2003 (e.g., CA), and
  - UCMR-1 method 314 is prone to false detections and interferences

An initial thought - PSG's recommendations on occurrence are premature as we have yet the review the model, let alone, the vet or review the MCLG approach. Also, I believe that our updated draft Occurrence Report addresses these issues which will be subject to public notice and comment at a later date as part of the perchlorate regulatory action.

I can draft a response highlighting responses to their peer review recommendations then send it to Russ for review unless you would like us to take a different direction.

Thanks,

Dan

Subject: Perchlorate Peer Review - Final Attachments for Thursday's Meeting on the Selection Report
Attachments: TO 2015-22 Proposed Reviewer Selection Report.pdf; TO 2015-22 CV NOM 001.doc; TO 2015-22 CV NOM 002.pdf; TO 2015-22 CV NOM 007.docx; TO 2015-22 CV NOM 008.docx; TO 2015-22 CV Reviewer 02.pdf; TO 2015-22 CV Reviewer 03.pdf; TO 2015-22 CV Reviewer 07.doc; TO 2015-22 CV Reviewer 08.pdf; TO 2015-22 CV Reviewer 10.DOC; TO 2015-22 CV Reviewer 12.docx; TO 2015-22 CV Reviewer 13.docx; TO 2015-22 CV Reviewer 15.doc

The peer review selection report attached has some very minor changes from the draft report. The draft report we sent previously was distributed before the close of the comment period to allow adequate advance time for review. One comment was received at the very end of the comment period, but it does not provide any comments specific to any individuals listed as interim reviewers. The document has been updated to acknowledge that one comment. It also incorporates all the appendices into one document. There are no other changes of any substance.

I'm also attaching the CV's of the reviewers in case anyone wants to look at that level of detail.

Thanks,
Russ

Subject: Perchlorate BBDR Model Peer Review Selection Report
Attachments: TO 2015-22 Draft Reviewer Selection Report to EPA 10.19.16.pdf; Appendix D Biosketches 10.19.16.pdf; Appendix C Reviewer Information 10.19.16.pdf; Appendix B COI Certification Letter 10.19.16.pdf

Tom – I've reviewed this selection report prepared by the contractor for the perchlorate BBDR model peer review and find it acceptable for distribution to the meeting attendees. Be advised that the comment period on the list of interim peer reviewers runs through October 21. Since you need the materials now (in advance of the comment close date) to provide adequate time for review, I instructed the contractor to place a "draft" mark on the document. If there are comments received before the end of the comment period, it is possible that some modifications will be needed. We will make you aware of any changes, if needed, early next week.

From your email yesterday, I'm assuming you or others in your office will attach the documents to the calendar entry for the meeting or otherwise will distribute to the total list of meeting attendees. If you want me to send it to the whole list, Please let me know. I'm just copying Mary and Francesca per your instructions along with my branch chief and the perchlorate team lead. **Since you indicate you are in a meeting today, I'd appreciate it if Mary or Francesca reply to me this morning if I am to distribute it to all attendees.**

Since an exact date has not been selected for the panel meeting and due to the range in expertise we are seeking, I asked the contractor to provide eight names for the final panel along with several alternates having varied expertise (primarily in the event that the precise date selected conflicts with a reviewer's availability).

Regards,
Russ

FIGURES

American Water Works Association is the authoritative resource for knowledge, information and advocacy to improve the quality and supply of water in North America and beyond. AWWA is the largest organization of water professionals in the world. AWWA advances public health, safety and welfare by uniting the efforts of the full spectrum of the entire water community. Through our collective strength we become better stewards of water for the greatest good of the people and the environment.

The Water Research Foundation (formerly Awwa Research Foundation) is a member-supported, international, nonprofit organization that sponsors research to enable water utilities, public health agencies, and other professionals to provide safe and affordable drinking water to consumers.

Water Industry Technical Action Fund (WITAF) is administered by AWWA and is funded through member dues. WITAF funds information collection and analysis and other activities in support of sound and effective legislation, regulation, and drinking water policies and programs.

ACKNOWLEDGMENTS

This report was funded by the American Water Works Association, Water Industry Technical Action Fund (WITAF) and the Water Research Foundation. The research team greatly appreciates the diligent efforts of the Southern Nevada Water Authority's (SNWA) Applied R&D Center (ARDC). Specifically, we wish to acknowledge Oscar Quiñones, Brett Vanderford, Doug Mawhinney, and Beck Trenholm for their assistance with the development and troubleshooting of the analytical methods employed throughout this project. In addition, we would like to thank Shanon Fergusson, Elaine Go, Christy Meza, Josephine Chu, and Janie Zeigler for assistance with the sample handling and preparation. We also wish to thank David Rexing, Linda Parker, and Ron Zegers for their support and assistance through the project.

The research team would like to acknowledge Kevin M. Morley of the American Water Works Association and Alice Fulmer of the Water Research Foundation for their relentless leadership and guidance throughout the project. The team also wishes to thank the Project Advisory Committee members for their thoughtful insight and careful review of our project reports:

Gary Lynch, Park Water Company
Robert Cushing, Carollo Engineers
Andrew Eaton, MWH Laboratories
Gary Emmert, University of Memphis
Richard Sakaji, East Bay MUD

The team is especially appreciative of the support of the participating manufacturers and utilities for providing water samples, hypochlorite samples, and information regarding equipment and operations:

MIOX Corporation
Severn Trent Services
Arch Chemical

EXECUTIVE SUMMARY

INTRODUCTION

The use of chlorine for the disinfection of water has arguably saved more human lives than any other public health action in history, with a legacy dating back over 150 years. Since chlorine's first use in 1846 at a hosipital in Vienna, Austria to prevent the spread of "child bed fever", many applications of the chemical have been explored including the first full scale chlorine installation for drinking water disinfection in Chicago in 1908. During the 100 years since its use in drinking water disinfection, chlorination and filtration of drinking water has been estimated to be responsible for a 50% increase in life expectancy. Today, 98% of North American community water treatment systems use chlorine for disinfection[1],[2].

Sodium hypochlorite is a commonly used form of chlorine in drinking water and water reuse applications for its ability to disinfect and maintain a residual level of disinfectant throughout the distribution system. Approximately 1/3 of all drinking water treatment plants (DWTPs) in the United States use bulk hypochlorite for disinfection. Though the majority of liquid hypochlorite use is in the form of bulk hypochlorite delivered from regional manufacturers and/or destributors, around 8% of US DWTPs use on-site hypochlorite generators (OSG). Additionally, due to security concerns associated with chlorine gas use, additional utilities may opt or be required to switch from their current disinfection practices to bulk or OSG hypochlorite.

Hypochlorite is known to contain various impurities, including bromate, chlorate, and chlorite. These contaminants may be present during manufacturing and/or may form during transport and storage. Recently, perchlorate has been detected at elevated levels in hypochlorite solutions. Considering that perchlorate is under consideration for Federal regulation and is currently regulated in California, New Jersey, and Massachusettes[3], it is critical that contribution of perchlorate from hypochlorite solutions be quantified. Bromate is another contaminant of hypochlorite solutions that may impact drinking water quality. Although bromate is regulated by a primary enforcable standard under the Safe Drinking Water Act, the regulated level could be lowered during the 6-year review process.

With these considerations in mind, our research team developed a plan to investigate the factors impacting the formation of perchlorate, bromate, and other contaminants in hypochlorite solutions and to develop a set of guidelines to assist utilities in minimizing the formation of such contaminants. Our project objectives also included the development of a detailed chemical rate law from which predictions could be made reagarding the formation of perchlorate in a given bulk hypochlorite solution.

RESEARCH OBJECTIVES

Based upon conversations with the Water Research Foundation Project Advisory Committee (PAC) and in accordance with specific objectives from within the AWWA RFP, the Project Team identified the following primary research objectives designed to provide the data necessary to determine the mechanisms, and to develop a predictive model, for perchlorate formation in hypochlorite solutions:

1. Determine the analytical method(s) most appropriate for measurement of oxyhalide anions in bulk hypochlorite solutions, OSG solutions, and utility water samples.

2. Determine the impact of co-occurring oxyhalide anions on the formation of perchlorate.

3. Determine the impact of pH, ionic strength, transition metals, and temperature on perchlorate formation.

4. Determine the detailed chemical rate law to predict perchlorate formation in hypochlorite solutions.

Additional secondary objectives were also developed to address concerns regarding operational considerations (i.e., hypochlorite sources, on-site generation, and other factors):

5. Compare perchlorate concentrations in bulk hypochlorite and different OSG systems, including those operated in mixed oxidant mode.

6. Determine the contribution of perchlorate in finished waters originating from hypochlorite addition.

7. Provide recommendations for water utilities to minimize the presence of perchlorate, bromate, chlorate, and chlorite in hypochlorite solutions.

RESEARCH APPROACH

In order to address the objectives outlined above, the Project Team designed a four-tiered approach to completing the project in less than one year. The specific tasks from the research approach were as follows:

Task 1: Comprehensive Literature Review
Task 2: Analysis of Impurities in Hypochlorite
Subtask 2.1: Perchlorate in Commercially Available Hypochlorite
Subtask 2.2: Impact of transition metals on perchlorate formation
Subtask 2.3: Determination of Factors Related to Perchlorate Formation and Minimization in Hypochlorite
Task 3: Treatment/Manufacturing System Impact on Drinking Water
Task 4: Recommendations and Final Report

These tasks are discussed in detail in Chapter 1 of this report. In short, a detailed (though dynamic) experimental matrix was designed to test how variables such as hypochlorite concentration, chlorate concentration, ionic strength, bromide and/or bromate, transition metal ions, pH, and temperature would impact the rate of perchlorate formation. Most of the initial experiments were designed to be run at elevated temperatures (60 °C) in order to provide rapid feedback regarding the impact of individual variables of perchlorate formation. In this manner, short incubation studies (e.g., 15 to 30 days) were used to design follow-up experiments at lower temperatures (thus longer incubation times of up to 200 days) targeting specific variables likely to have the most effect on perchlorate formation. In total, over 5000 data points were collected. These data were used to validate methods, elucidate the mechanism of perchlorate formation, build a detailed chemical rate law, and to validate the rate law on utility and OSG hypochlorite samples. Seven water treatment utilities, two OSG manufacturers, and one calcium hypochlorite supplier participated in this study, providing samples from five different bulk hypochlorite suppliers, 12 OSG systems, and one solid calcium hypochlorite sample.

REPORT OVERVIEW

This Final Report is divided into 6 Chapters, each of which is designed to carry the reader through the scientific process behind developing the "Predictive Model" and the specific recommendations for minimizing the formation of perchlorate in stored hypochlorite solutions.

- Chapter 1 contains background information on occurrence, regulation, and hypothesized mechanisms of formation for perchlorate and other regulated and non-regulated contaminants of hypochlorite solutions. This Chapter also provides a context for the current study and outlines the research approach in detail.

- Chapter 2 describes the development of analytical methods and subsequent validation of analytical methods used for the identification and quantification of perchlorate, chlorate, and bromate within concentrated hypochlorite solutions. This chapter also provides methodologies applied for other contaminants previously identified in hypochlorite.

- Chapter 3 examines the factors which influence the rate of perchlorate formation in hypochlorite solutions. Key factors identified include, hypochlorite ion concentration, chlorate ion concentration, ionic strength, and temperature.

- Chapter 4 describes the development and validation of the detailed chemical rate law which is applied for predicting the concentration of perchlorate in a given bulk hypochlorite solution.

- Chapter 5 provides the results of a survey of bulk and OSG hypochlorite solutions obtained from various manufactures and facilities for perchlorate, chlorate, and bromate. This chapter also provides the application of the rate law to predict perchlorate concentration in hypochlorite.

- Chapter 6 summarizes the findings of the study and provides recommendations to utilities on how to minimize the formation of perchlorate in bulk hypochlorite.

CONCLUSIONS

Robust analytical techniques were developed to determine the concentration of perchlorate, chlorate, and bromate in concentrated hypochlorite solutions. An LC-MS/MS method was used for all perchlorate and bromate analyses. Both LC-MS/MS and titration methods were successful for chlorate analysis; however, LC-MS/MS was found to be more robust in hypochlorite solutions with free available chlorine (FAC) < 5%, while titration was found to be superior in hypochlorite solutions containing > 5% FAC.

The formation of perchlorate occurs over time as hypochlorite degrades, while bromate is rapidly formed during hypochlorite manufacturing and does not change significantly over time. The formation of perchlorate is impacted by several key factors including:

- Direct factors such as hypochlorite and chlorate concentration, ionic strength, and pH
- Indirect factors such as metal ions and bromide concentration
- Environmental factors such as temperature

Considering the variables and experimental boundaries described in this report, perchlorate formation was found to be first order in both hypochlorite and chlorate ion concentration and is highly dependent upon ionic strength and temperature. These factors were used to develop a predictive model for perchlorate that was found to agree within 10% of measured values within the boundary conditions established in this study (i.e., pH 11 – 13 and temperatures to 50° C). It should be noted, however, that in order to validate a predictive model at any temperature, a minimum of at least 1.5 half-lives are required. For the perchlorate predictive model at temperatures below 30 °C, the time required to reach at least 1.5 half-lives would have exceeded the time allotted for the study. Thus, while the model has been validated between 30 °C and 50 °C, any information gathered from lower temperatures should be limited to qualitative information only until low-temperature studies can be completed.

Finally, a set of 5 bulk hypochlorite solutions, 12 OSG hypochlorite solutions, and one calcium hypochlorite sample was obtained for contaminant analysis and quantification and was used in a holding study to examine the rate of perchlorate formation in each solution. All samples tested had measurable concentrations of chlorate, perchlorate, and bromate. No specific conclusions could be made regarding differences in contaminant concentrations in bulk, OSG, and calcium hypochlorite solutions. There did appear to be, however, a link between salt quality and bromate concentration in OSG samples, suggesting that a salt of a higher purity (in this study, >99.5% as NaCl) may be useful for reducing the amount of bromate in the hypochlorite product. However, this trend needs to be further investigated before a specific recommendation on salt purity and maximum levels of bromide can be quantified. When the various solutions were aged, good correlation was observed between the rate of perchlorate formation, the concentration of hypochlorite and chlorate ions, and ionic strength. Furthermore, the "Predictive Model" was able to predict perchlorate formation in the bulk hypochlorite samples to within 20% of the measured concentration for up to 28 days at 50 °C.

RECOMMENDATIONS

Based on the findings presented in this report, several key factors have been identified that impact the formation of perchlorate, bromate, and other contaminants in hypochlorite solutions. The major factors impacting perchlorate formation parallel those previously described for reducing the decomposition of hypochlorite: temperature, ionic strength, concentration, and pH. By using the information gathered during this study and by applying the "Predictive Model" to hypothetical liquid hypochlorite storage scenarios, several quantitative and qualitative recommendations can be made:

a. Dilute stored hypochlorite solutions upon delivery: The decomposition of hypochlorite and subsequent formation of chlorate and perchlorate is dependent upon hypochlorite concentration and ionic strength. Higher ionic strength and hypochlorite concentration will drive the reaction towards a greater production of chlorate and perchlorate while also increasing the rate of decomposition of hypochlorite. By diluting a 2 molar hypochlorite solution by a factor of 2, the rate of perchlorate formation decreases by a factor of 7 due to the combination of concentration and ionic strength effects. A four-fold dilution of a hypochlorite solution will decrease the rate of formation by 36. A ten-fold dilution of a hypochlorite solution will decrease the rate of perchlorate formation by a factor of 270.

b. Store the hypochlorite solutions at lower temperatures: Higher temperatures speed up the chemical decomposition of hypochlorite and the subsequent formation of chlorate and perchlorate. Every 5 °C reduction in storage temperature will reduce the rate of perchlorate formation by a factor of approximately 2.

c. Control the pH of stored hypochlorite solutions at pH 11 – 13, even after dilution: Storage of concentrated hypochlorite solutions at pH values lower than 11 is not recommended due to rapid decomposition of hypochlorite ion/hypochlorous acid and the consequent formation of chlorate even though this reduces the amount of perchlorate formed. When the pH is higher than 13, perchlorate formation is enhanced due to the ionic strength effect. As such, utilities should continue to insist that manufacturer specifications include pH control in the range of 11 to 13. Given the typical pH range of OSG hypochlorite (pH 9 to 10), such solutions should be used as soon as possible after manufacture and should not be stored for more than 1-2 days.

d. Control the removal of transition metal ions by purchasing filtered hypochlorite solutions and by using low-metal ion concentration feed water for the OSG systems: The presence of transition metal ions results in an increased degradation rate of hypochlorite. While this degradation is concomitant with reduced perchlorate formation, the FAC concentration is also reduced, forcing a utility to use a higher volume of a hypochlorite solution which results in higher mass loading of contaminants such as perchlorate, chlorate, and bromate.

e. Use fresh hypochlorite solutions when possible: Over time, hypochlorite will naturally decompose to produce oxygen, chlorate, and perchlorate. Less storage time

will minimize the formation of these contaminants in the hypochlorite solution. A fresh hypochlorite solution will also contain a higher concentration of hypochlorite, thereby reducing the amount of solution required to obtain the target chlorine residual. Again, higher hypochlorite concentration in a fresh hypochlorite solution will correspond to lower concentrations of contaminants dosed.

f. For utilities using OSG hypochlorite, use low-bromide salt to minimize the amount of bromide present in the brine: Bromate formation will occur rapidly in hypochlorite solutions in the presence of bromide. By controlling the amount of bromide in the salt and source water used for on-site generation, bromate formation can be minimized.

If a utility were to combine dilution with temperature reduction, a significant impact on hypochlorite decomposition and perchlorate formation would be observed. For example, as described in Chapter 4 if a utility were to dilute a 13% bulk hypochlorite solution by a factor of 2 and also reduce the storage temperature by 10 °C, the result would be 16 times less hypochlorite decomposition and 27 times less perchlorate formation than if the hypochlorite were stored at ambient temperatures undiluted. Chapter 4, Table 4.8 details the combined effects of temperature and dilution for various storage scenarios.

Another interpretation of the results of this study is through seasonal trends. If, for example, a utility experienced average bulk hypochlorite storage temperatures of 10 °C in the winter and 35 °C in the summer, the rate of perchlorate formation for 13% hypochlorite would be nearly 18 times faster in the summer. In other words, in winter that utility could expect the concentration of perchlorate concentration to increase by a factor of 10 in approximately 3 months; in summer it would increase by a factor of 10 in only 5 days. Had the hypochlorite solution been diluted by a factor of 2, the same increase in perchlorate concentration would take one month in summer and 20 months (assuming, for example, an average temperature of 10 °C) in winter. Therefore, in order to minimize the amount of perchlorate formation in hypochlorite solutions, a combination of dilution and temperature control is recommended.

QUESTIONS FOR UTILITIES TO ASK BULK HYPOCHLORITE AND OSG SUPPLIERS

Based upon the findings of this study, a series of questions have been developed to assist utilities in developing questions that they may wish to ask hypochlorite manufacturers. While these questions are not meant to preclude or give advantage to any manufacturer or process, they are meant to help utilities obtain the information that might be of use to them in deciding how to store and handle the hypochlorite solutions that they purchase or produce on-site.

Questions for Bulk Hypochlorite Manufacturers

1. What is the temperature of the hypochlorite solution directly after manufacture?
2. At what temperature is the hypochlorite solution stored between manufacture and delivery?
3. Is there a cooling system in place to lower the temperature of the final product at the manufacturing facility?
4. Do the delivery vehicles have any cooling systems in place to hold the hypochlorite solution at a constant temperature during transport?

5. What is the concentration of hypochlorite at the time of delivery? If unknown, can the manufacturer provide the concentration of hypochlorite at the time of manufacture together with the age and storage conditions of the hypochlorite solution?
6. Do they know the concentration of bromate, chlorate, and perchlorate in the hypochlorite solutions? If so, will they provide that information?
7. What is the ionic strength of the hypochlorite solution at the time of manufacture? Does the manufacturer offer any means to reduce the ionic strength?
8. What quality of salt is used during the manufacturing process? How much bromide is present in the salt?
9. What is the concentration of transition metals (nickel, manganese, iron, cobalt, and copper) are present in the hypochlorite solution? Do these values fall within the NSF specifications for metals?
10. Does the manufacturer offer filtered hypochlorite solutions?

Questions for On-Site Generator Manufacturers

1. Does the OSG manufacturer have any specific recommendations about quality or source of salt?
2. Do they know of any specific impurities in salt that can adversely impact OSG operation or formation of contaminants in the hypochlorite solution product?
3. Does the OSG manufacturer know the range of perchlorate concentration in the final OSG solution for their various models?

Questions for Salt Suppliers

1. What is the source of the salt being delivered?
2. What is the purity (as NaCl) of the salt delivered?
3. What is the concentration of bromide in the salt?
4. What concentration of transition metals (nickel, manganese, iron, cobalt, and copper) is present in the salt?

CHAPTER 1
INTRODUCTION

BACKGROUND

Sodium hypochlorite (a.k.a. "bleach") is commonly used in drinking water and water reuse applications for its ability to disinfect and maintain a residual level of disinfectant throughout the distribution system. Multiple regulated contaminants exist in hypochlorite solutions including bromate, hypochlorite itself, and chlorite (Gordon, Pacey, and Bubnis 1993; Weinberg, Delcomyn, and Unnam 2003; Chlorine_Institute 2004; Asami, Kosaka, and Kunikane 2009) in addition to other unregulated oxyhalides such as chlorate and perchlorate. The presence of such oxyhalides in drinking water has become a major issue of concern for the water industry. Recently, perchlorate has been identified as a contaminant of concern in hypochlorite solutions and has received a large amount of attention as it is an endocrine disrupting compound which can impact the thyroid system of humans (Lamm, et al. 1999; Urbansky 2000a; York, et al. 2001; Greer, et al. 2002b).

Perchlorate is both a natural and anthropogenic compound: perchlorate has been found to occur naturally in the US and Chile (Dafert 1908; Jackson, et al. 2005) and has also been manufactured and used as an oxidizer for solid fuel engines, fireworks, and road flares (Davis 1940; Hampel and Leppla 1947; Simchen and Inbar-Rozem 1968; Urbansky 2000a). Chilean nitrate, a source of naturally occurring perchlorate, has been used for many years in agricultural applications in the United States. Where large quantities of perchlorate have been produced or used, perchlorate contamination of soil and water has been detected, with concentrations approaching 3,000 mg/L at former industrial sites in the Las Vegas valley. Modern analytical instrumentation has facilitated the detection of perchlorate in drinking water, dairy products, human breast milk, plants, fish, and cattle (Urbansky, et al. 2000b; Kirk, et al. 2003; Sundberg, et al. 2003; Cheng, et al. 2004; Dodds, et al. 2004; Yu, et al. 2004; Kirk, et al. 2005; Sanchez, et al. 2005; Snyder, Vanderford, and Rexing 2005). Perchlorate has also been detected in kelp (Orris, et al. 2003; Martinelango, Tian, and Dasgupta 2006), which is often used as a source of iodine in dietary supplements (Turrentine 1924; Teas, et al. 2004).

In 2002 the US EPA published a reference dose (RfD) for perchlorate of 0.00003 mg/kg/day, which would suggest drinking water equivalent level (DWEL) of approximately 1 µg/L (USEPA 2002; Tiemann 2008). In 2005 the National Academy of Sciences and the US EPA updated the RfD to 0.0007 mg/kg/day with a DWEL of 24.5 µg/L (USEPA 2006), a number based on the no observable effect level (NOEL) of 0.007 mg/kg-day for inhibition of iodide uptake determined in a human clinical trial (Greer, et al. 2002a). Despite coming forward with an updated RfD, it is unclear whether or not perchlorate will be regulated nationally at this time (Swackhamer and Rose 2008; Tiemann 2008). However, the state of Massachusetts has set a DWEL and maximum contaminant level (MCL) of 2.0 µg/L for perchlorate (MA_DEP 2006), and California has established a MCL of 6.0 µg/L (CA_DPH 2007). Based on data from this study and data published elsewhere, perchlorate appears to be a ubiquitous contaminant of hypochlorite solutions and the perchlorate concentration in hypochlorite increases significantly over time (Greiner, et al. 2008; Asami, Kosaka, and Kunikane 2009).

Chlorate is a contaminant produced during on-site generation of hypochlorite solutions and the subsequent decomposition of hypochlorite. Chlorate is also a by-product of treatment of drinking water with chlorine dioxide (USEPA 1999; Snyder, Vanderford, and Rexing 2005).

Toxicological reports have shown that chlorate has similar toxic modes of action as the unregulated contaminant perchlorate. The state of California has set an action level for chlorate in drinking water of 800 µg/l (Drinking Water Notification Levels 2004); an action level as low as 200 µg/l has been suggested (Howd 2002). The World Health Organization has set a guideline MCL of 700 µg/L (WHO 2008). Chlorate exhibits the same mechanism of action on the thyroid as perchlorate, albeit with lower potency (USEPA 1999; Pleus 2000; Hooth, et al. 2001). Chlorate has been shown to occur in bottled water and in municipal drinking water at levels up to 270 µg/l (Snyder, Vanderford, and Rexing 2005). Chlorate occurs in drinking waters at levels much greater than those reported for perchlorate, thus, even though it is less potent than perchlorate, its toxicological relevance and occurrence is significant in holistic exposure assessments of goitrogens.

Bromate is another possible contaminant of hypochlorite solutions (Asami, Kosaka, and Kunikane 2009) and results from the oxidation of bromide to hypobromite to bromate via a mechanism analogous to that of chlorate. Bromate may also form during ozonation when bromide is oxidized by dissolved ozone in water. Bromate has been reported to be a carcinogen in mammalian studies (Kurokawa, et al. 1986; DeAngelo, et al. 1998) and is suspected to have a role in oxidative DNA damage in target organs (Ballmaier and Epe 1995; Chipman, et al. 1998). Bromate is currently regulated by the US EPA in drinking water at an MCL of 10 µg/L and is specified in hypochlorite solutions not to exceed 0.5 µg BrO_3^-/mg FAC (NSF/ANSI 2005).

Given the high likelihood of finding perchlorate (in addition to chlorate, chlorite, and bromate) in hypochlorite solutions and the widespread use of hypochlorite, the potential contribution of perchlorate from hypochlorite is a critical issue to understand. To exacerbate this situation, some utilities that once used gaseous chlorine are moving to the use of hypochlorite solutions due to homeland security concerns related to chlorine gas. The potential health impacts of perchlorate have been widely debated in the public media, and it is likely that additional states will begin to regulate perchlorate in drinking water independent of any US EPA regulatory determinations. Thus, it is vital that the water industry has the predictive tools available to understand how much perchlorate is added to drinking waters from hypochlorite and what measures can be taken to minimize the formation of perchlorate in hypochlorite solutions.

BULK HYPOCHLORITE MANUFACTURING AND USE IN DRINKING WATER TREATMENT

Of the drinking water treatment plants (DWTPs) in the United States, approximately 31% use bulk hypochlorite solutions for disinfection and 63% use chlorine gas (Routt 2008; Routt, et al. 2008). Additionally, 8% of US DWTPs use on-site generators (OSGs) for electrolytical sodium hypochlorite production from brine solutions and 8% use calcium hypochlorite (note that utilities may use more than one process for disinfection, thus numbers do not total 100%). There are multiple suppliers with multiple configurations of OSG systems including MIOX Corporation, Severn Trent (ClorTec), US Filter, and others and there are equally as many suppliers of bulk hypochlorite. It is generally manufactured by passing chlorine gas through sodium hydroxide. Sodium hydroxide is frequently produced by means of the chlor-alkali process, in which an aqueous sodium chloride solution is electrolyzed to produce chlorine gas and sodium hydroxide (Gordon, et al. 1993; Gordon, Pacey, and Bubnis 1993; Gordon, Adam, and Bubnis 1994; Gordon, Adam, and Bubnis 1995). In this context it should be noted that there are only five remaining chlor-alkali mercury cell systems still manufacturing sodium hydroxide

in the United States (Oceana 2007). However, unlike the myriad configurations for OSGs, the majority of bulk hypochlorite suppliers utilize either a Powell Fabrication Generator and/or batch process. OSGs, on the other hand, vary much more widely in terms of the chemical composition of electrode materials, energy inputs, configuration, feed water quality, and salt quality. Different OSGs also have inter- and intra- brand differences. Thus, bulk hypochlorite tends to be more uniform in quality and production methods than OSG hypochlorite. Another major difference between bulk hypochlorite and OSG hypochlorite is in the concentration of hypochlorite produced: bulk hypochlorite is typically delivered as a 13% hypochlorite solution while OSG hypochlorite ranges from less than 1 % free available chlorine (FAC) to 4 % FAC.

Other sources of chlorine are available to DWTPs including calcium hypochlorite, chlorine gas, and chlorine dioxide. Calcium hypochlorite (in solid form) should, theoreticaly, have a longer shelf life than liquid hypochlorite as the decomposition of hypochlorite requires an aqueous solution. However, calcium hypochlorite is typically used only as an emergency back-up process or in small-scale operations due to increased maintenance and water hardness issues associated with its use. Chlorine dioxide is another alternative to hypochlorite which has been shown to help reduce the formation of trihalomethanes (THMs) though may be associated with increased chlorite concentration in finished water (McGuire, Lieu, and Pearthree 1999). Chlorine gas is another popular option for disinfection of drinking water and is currently used by approximately 60% of DWTPs in the United States. Because of the low concentration of dissolved chlorine gas, appreciable quantitites of perchlorate, chlorate, and chlorite are not expected to form. There are, however safety and security issues associated with handling, storage, and application. Thus, many utilities currently using chlorine gas are considering the implications of switching to the use of hypochlorite, both from a cost perspective and from a contaminant perspective.

REGULATED AND UNREGULATED CONTAMINANTS OF HYPOCHLORITE SOLUTIONS

With the differences in concentration and production processes associated with hypochlorite solutions is a concomitant difference associated with the presence and formation of contaminants. For example, small quantities of transition metal ions such as nickel(II), copper(II), manganese(II), cobalt(II) and iron(III) may be present in unfiltered finished hypochlorite solutions. Small concentrations of these ions (on the order of 1 to 2 mg/L) have been shown increase the rate of decomposition of hypochlorite by as much as 1 to 2 orders of magnitude (Gordon, Adam, and Bubnis 1994; Gordon, Adam, and Bubnis 1995) and have been hypothesized to play a catalytic role in the formation of perchlorate. Interestingly, perchlorate is also produced through an electrolytic process where chlorate may be oxidized to perchlorate (Urbansky 2000a), a distinct possibility in electrolytic hypochlorite manufacturing processes. Snyder, Vandeford, and Rexing (2005) reported that perchlorate was measurable in hypochlorite originating from an on-site hypochlorite generator. The Japanese National Institute of Public Health (JNIPH) reported that as a commercially available hypochlorite solution decayed, perchlorate concentration increased (Asami, Kosaka, and Kunikane 2007). Likewise, the JNIPH also noted that perchlorate concentration was relatively low in hypochlorite solutions produced by on-site generation. Generally speaking, however, there is little additional quantitative data regarding the concentration of perchlorate in hypochlorite solutions. To the best of our knowledge, neither have any reports been published that provide hard evidence regarding the

kinetics of perchlorate formation, nor have any reports discussed ways to minimize its formation in hypochlorite.

Chlorate and chlorite, on the other hand, are well known degradation products and contaminants of hypochlorite solutions and are present in all hypochlorite (Gordon, Adam, and Bubnis 1995). Chlorate is currently unregulated at the Federal level (though the World Health Organization has set a guideline MCL of 700 µg/L) while chlorite is Federally regulated in drinking water by the US EPA with an MCL of 0.8 mg/L. Hypochlorite ion is unstable and undergoes two independent modes of self-decomposition. In one mode, oxygen and chloride are formed and in the other mode, chlorate and chloride are formed:

$$2OCl^- \rightarrow O_2 + 2Cl^- \quad \textbf{(1.1)}$$

$$3OCl^- \rightarrow ClO_3^- + 2Cl^- \quad \textbf{(1.2)}$$

The rate of decomposition of hypochlorite to form chlorate and/or oxygen is well defined in terms of the following rate law:

$$\frac{d[OCl^-]}{3dt} = k_{obs}[OCl^-]^2 \quad \textbf{(1.3)}$$

Chlorite is rapidly formed as a steady state species (not shown) in Equation 2 that serves as an intermediate between hypochlorite and chlorate. The typical half-life for decomposing 12 to 13 weight % hypochlorite (OCl^-) at room temperature (25°C) is on the order of 150 to 160 days (Gordon, et al. 1997). Changes in temperature also markedly affect the rate of decomposition of hypochlorite solutions. For example, an increase of 10 °C will increase the rate of decomposition by a factor 3.5 to 4.0. As previously mentioned, 1 to 2 mg/L of transition metal ions increase the rate of decomposition of hypochlorite by as much as 1 to 2 orders of magnitude (Gordon, Adam, and Bubnis 1994; Gordon, Adam, and Bubnis 1995), thereby impacting the formation of chlorate as well. With different types of contaminants present in hypochlorite and the specific storage conditions (e.g., temperature, pH) one reaction pathway may be favored over another, thereby potentially creating more chlorate and perchlorate in the process. Furthermore, the formation of perchlorate has been hypothesized elsewhere to be a direct result of reactions between hypochlorite and chlorate as the solution decomposes (Asami, Kosaka, and Kunikane 2007; Asami, Kosaka, and Kunikane 2009).

Bromate is another contaminant typically associated with ozonation of bromide-containing waters, though it can also be found in hypochlorite solutions likely from a reaction of bromide with hypochlorite analagous to the formation of chlorate (Asami, Kosaka, and Kunikane 2009). Better refining of salts and/or source water for hypochlorite generation may help remove or reduce the introduction of bromide into the process and final product thereby greatly reducing the amount of bromate formed. It is currently unknown what impacts the presence of bromite and/or bromate will have on the decomposition of hypochlorite and the formation of chlorate and perchlorate in those solutions.

ANALYTICAL METHODS

Prior to 2005, the most commonly applied instrumental analytical technique for measurement of oxyhalide anions was ion-chromatography with conductivity detection (IC-CD). Of those, US EPA methods 300.1 and 314 using IC-CD were the most commonly used methods for the analysis of bromate and perchlorate with reporting limits of 5 µg/L for bromate and 4 µg/L for perchlorate. While IC-CD was successfully applied to many drinking waters, obtaining reliable results in more concentrated samples with higher conductivity was challenging. Furthermore, these methods suffered from potential matrix interferences when applied to environmental mixtures (Urbansky 2000b; Anderson and Wu 2002; Liu, Mou, and Heberling 2002). For example, p-chlorobenzene sulfonate, a compound often found in paints and chemical manufacturing, co-elutes with perchlorate when analyzed by US EPA method 314 (IC-CD method) and interferes with quantitation. (Johnson, Grimshaw, and Richman 2003). Some techniques used to overcome these challenges included pre-concentration steps, such as solid-phase extraction (SPE) and ion-exchange columns, and post-column reactions (derivatizations) followed by UV measurement (IC-PCR) (Inoue, et al. 1997; Bichsel and Von Gunten 1999; Nowack and von Gunten 1999; Salhi and Von Gunten 1999; Magnuson, Urbansky, and Kelty 2000; Urbansky, et al. 2000a; Wagner, et al. 2002; Kirk, et al. 2004). A more sensitive method for bromate analysis was US EPA method 317 using IC-PCR with a reporting limit around 1 µg/L though it was not applicable to other oxyhalides except chlorite. Other approved methods for bromate analysis include US EPA methods 326 and 321.8.

Other non-instrumental approaches to measuring perchlorate and other oxyhalides in aqueous media have included colorimetric determination (Bodenheimer 1955), spectrophotometric determination (Fritz 1964; Prince 1964; Cheng 1967; Weiss 1972), atomic absorption (Collinson 1968), UV absorbance (Soto, et al. 2008), amperometric titration (Clesceri, Greenberg, and Eaton 1998), and direct titration (Adam and Gordon 1995). The direct titration method relies upon the reduction of hypochlorite with sulfite, followed by sequential reduction of chlorite and chlorate ions with iodide, resulting in the stoichiometric production of iodine ions. This allows determination of these ions by iodometry, where the proportional amount of iodine for the reactions with the analyte is titrated with a standardized thiosulfate solution. One advantage of potentiometric methods over IC-CD methods is the selectivity towards specific oxyhalide anions and the ability of the method to be applied to concentrated hypochlorite solutions.

Mass spectrometry is another technique that has been applied for the detection of oxyhalide anions, most commonly in conjunction with ion-chromatography (IC-MS) or liquid chromatography (LC-MS) (Salov, et al. 1992; Urbansky, et al. 1999; Handy, et al. 2000; Koester, Beller, and Halden 2000; Magnuson, Urbansky, and Kelty 2000; Roehl, et al. 2002; Winkler, Minteer, and Willey 2004). The use of mass spectrometry for the detection of ionic compounds increased dramatically with the development of commercially available IC-MS systems (Zwiener and Frimmel 2004). In order to obtain accurate quantitation using IC-MS or LC-MS techniques, many investigators used clean-up techniques to minimize interfering compounds (Urbansky 2000b) or standard addition to compensate for suppression/enhancement artifacts (Batista, McGarvey, and Vieira 2000; Koester, Beller, and Halden 2000; Magnuson, Urbansky, and Kelty 2000). The use of tandem mass spectrometry (MS/MS) and isotope dilution can also be used to add selectivity and accuracy to oxyhalide quantitation methods. US EPA method 331.0 uses LC-MS/MS while US EPA method 332.0 uses IC-MS/MS to detect perchlorate in water, but neither

was developed to identify and quantify other oxyhalides at the same time (USEPA 2005a; USEPA 2005b). A paper by Snyder et al. (2005) demonstrates that LC-MS/MS can be used to measure perchlorate together with bromate, chlorate, and iodate in OSG hypochlorite solutions (Snyder, Vanderford, and Rexing 2005). Furthermore, this paper demonstrates that, under the conditions employed, LC-MS/MS is capable of detecting perchlorate in commercial detergents – which is a significantly more challenging matrix than drinking water. This same method was later adapted to measure perchlorate in aqueous extracts of vitamins and food supplements (Snyder, et al. 2006).

RESEARCH QUESTIONS AND APPROACH

Based on the above considerations, conversations with the Water Research Foundation Project Advisory Committee, and specific objectives from within the AWWA RFP, the Project Team at SNWA identified the following additional research questions designed ultimately to assist the Project Team in determining a mechanism and predictive model for perchlorate formation in hypochlorite solutions:

1. What analytical method(s) is/are the most appropriate for measurement of oxyhalide anions in bulk hypochlorite solutions, OSG solutions, and utility water samples?

2. What hypochlorite quenching agent could be employed for use in sample preservation that would not interfere with the analysis of chlorite, chlorate, perchlorate, bromate, and metals?

3. What effects do the concentration of oxyhalide anions in addition to bromide have on the formation of perchlorate and bromate?

4. What effects do pH, ionic strength, and temperature have on perchlorate formation?

5. Do transition metals catalyze the formation of perchlorate in hypochlorite solutions?

6. Can a detailed chemical rate law be developed to predict (within 30 days of manufacture) perchlorate formation in sodium hypochlorite solutions to within +/- 10% of actual values?

7. What rate law best describes the formation of perchlorate in hypochlorite solutions and what is the reaction order with respect to hypochlorite, chlorate, and any other contributing anions?

8. Is a simple mechanism available to describe the formation of perchlorate from hypochlorite and chlorate?

Additional questions were also asked regarding operational considerations, hypochlorite sources, on-site generation, and other factors for DWTPs:

9. Is there a significant difference in the perchlorate concentration measured in fresh bulk hypochlorite and different OSG systems including those operated in mixed oxidant mode?

10. To what extend could the use of OSG or bulk hypochlorite adversely affect perchlorate concentration in finished drinking water considering the NSF 60 maximum use level (MUL) of 10 mg/L (NSF/ANSI 2005)?

11. What recommendations can be made to drinking water utilities to minimize the presence of perchlorate, bromate, chlorate, and chlorite in hypochlorite solutions used for drinking water treatment?

Research Approach

In order to answer the questions outlined above the Project Team designed a four-tiered approach to completing the project within the allowed 11-month period. The overarching objective of this study was to evaluate the magnitude of perchlorate contamination in chemically and electrochemically manufactured hypochlorite solutions, to determine the impact on finished drinking water contamination, to provide utilities with a way to predict perchlorate concentration in hypochlorite solutions, and to devise techniques to minimize the formation of perchlorate in hypochlorite solutions. The specific task outlined in the Project Proposal included the following:

Task 1: Comprehensive Literature Review
Task 2: Analysis of Impurities in Hypochlorite
Subtask 2.1: Perchlorate in Commercially Available Hypochlorite
Subtask 2.2: Impact of transition metals on perchlorate formation
Subtask 2.3: Determination of Factors Related to Perchlorate Formation and Minimization in Hypochlorite
Task 3: Treatment/Manufacturing System Impact on Drinking Water
Task 4: Recommendations and Final Report

Task 1: Literature Review

The initial phase of this study involved a review of available literature regarding hypochlorite and perchlorate chemistry, analytical methodologies, and current occurrence data. A significant portion of the literature review for this study was completed prior to the Project Kickoff (May 9, 2008) and was used to identify experiments necessary in the early stages of the project. The literature review was an ongoing process during the course of the Project whereby additional papers found in the literature were used to further refine the experimental matrix and guide the completion of this Final Report.

Task 2: Impurities Analysis

This Project Team had previously developed robust analytical methodologies that were able to identify and quantify accurately and precisely perchlorate in hypochlorite solutions at sub-µg/L concentrations (Snyder, Vanderford, and Rexing 2005). The methodology utilized LC-MS/MS technology with an isotopically labeled (^{18}oxygen) perchlorate as an internal standard.

The methods developed by SNWA researchers allowed for the simultaneous, direct LC-MS/MS measurement of perchlorate, chlorate, and bromate in hypochlorite solutions and drinking water samples. However, for the purposes of understanding the factors which impact the formation of perchlorate, the decision was made to devote several weeks at the beginning of the project towards determining whether the LC-MS/MS method or the titrimetric method would provide more accurate and precise quantitation. Once the method of choice was clearly identified for use in concentrated hypochlorite solutions, then the Project Team could focus on the mechanistic studies.

Subtask 2.1: Perchlorate in Commercially Available Hypochlorite Prior to collecting, shipping, and analyzing any hypochlorite samples, the effect that preservatives / quenching agents had on the presence, formation, or decay of any species of consideration (oxyhalides, chloride, bromide, and metals) had to be quantified. The commonly used quenching agent used to treat residual hypochlorite prior to mass spectrometric measurement of perchlorate ion had been hydrogen peroxide (Urbansky 2000c). However, it was not clear that the use of peroxide would be the best quenching agent for this study. Thus, a total of seven quenching agents (hydrogen peroxide, ascorbic acid, glycine, malonic acid, oxalic acid, sodium thiosulfate, and sodium sulfite) were tested for the removal (quenching) of hypochlorite and the impact on other contaminants of concern. The criteria for the best quenching agent included ease of handling, safety, rate of reaction with hypochlorite, absence of adventitious impurities in the quenching agent, and stability.

After selection of a quenching agent and analytical method, a series of commercially available hypochlorite solutions and OSG solutions were tested for perchlorate, bromate, bromide, and transition metals. Additionally, seven utilities were asked to provide hypochlorite and treated water samples for oxyhalide and metals analysis. A commercially available 13% sodium hypochlorite solution was chosen as the baseline for kinetics studies and was aged at different dilutions with varying concentrations of chlorate, chlorite, chloride, bromide, bromate, ionic strength, pH, and transition metals. Temperatures were varied for batch studies from 30 °C to 75 °C. In total, over 3,800 individual data points were collected for elucidation of the mechanism described in this Report. Similarly, over 1,500 individual data points were collected from the OSG and Utility hypochlorite samples, aged at 50 °C, and used to validate the model predictions. The study also included over 120 individual data points for the surveyed raw, finished, and distribution waters.

Subtask 2.2: Impact of transition metals on perchlorate formation In previous studies of the decomposition of hypochlorite to form chlorate, transition metal ions have been shown to have very important catalytic properties (Gordon, et al. 1993; Gordon, Adam, and Bubnis 1994; Gordon, Adam, and Bubnis 1995). Nickel ion, for example at the 1 – 2 mg/L level, was shown to enhance the rate of hypochlorite decomposition by more than a factor of ten. Other transition metal ions such as cobalt(II) and copper(II) may also impact the rate of hypochlorite loss though manganese(II) iron(II) seem to have little to no effect. These transitions metal ions represent those that are most likely to be present in commercial hypochlorite and potentially impact perchlorate formation. Thus, a series of experiments were also carried out as part of the concentration matrix (from Subtask 2.1) at 0.2, 2, and 20 mg/L of nickel(II), manganese(II), iron(II), cobalt(II), and copper(II). In addition, noble metals ions (Ag, Au, Ir, Pd, Pt) at 0.2 mg/L were also included as part of this task.

Subtask 2.3: Determination of Factors Related to Perchlorate Formation and Minimization in Hypochlorite This task was designed determine the factors in hypochlorite manufacturing and handling that would have the greatest impact on the formation of perchlorate in hypochlorite solutions. The Project Team used experiments from this task to assist in developing clear strategies for minimizing the formation of perchlorate in both hypochlorite manufacturing and on subsequent storage/handling. Temperature, hypochlorite concentration, and presence of metal ions were all investigated as each plays an important role in hypochlorite degradation (Gordon, Adam, and Bubnis 1994). Experiments under this task included aging hypochlorite solutions at various temperatures, pH, bromide, and metal ion concentrations, and collecting samples for perchlorate and bromate analysis as a function of time. The loss of hypochlorite and the formation of perchlorate were monitored during this portion of the study.

Task 3: Systems Impact (Influence of Hypochlorite in Perchlorate Contamination of Drinking Water)

This task was designed to provide a means for determining the degree of perchlorate contamination in finished drinking water attributable to hypochlorite. Specific experiments were designed to create a detailed chemical rate law ("Predictive Model") in order to understand the kinetic processes influencing the rate of perchlorate build-up in freshly prepared and aging hypochlorite solutions as a function of hypochlorite, chlorate, and chloride concentrations, pH, storage temperature, ionic strength, and metal ion concentration. The results of these experiments were used to develop a preliminary mathematical model from the detailed chemical rate law describing the role of each of the experimental variables in the formation of perchlorate along with the appropriate uncertainties (similar to the Adam and Gordon chlorate ion "Bleach 2001" model). The objective was to develop a "Predictive Model" that would take into account the sources of perchlorate (*e.g.*, the sodium hydroxide, the manufacturing of hypochlorite, and the continued decomposition of hypochlorite) as a function of hypochlorite, chlorate, chloride, and storage temperature and be used to assist in making specific, quantitative recommendations to utilities to minimize perchlorate formation. Additionally, several calculations were used to determine minimum, median, and maximum concentrations of perchlorate that could be expected at a typical water treatment facility based upon hypochlorite age, storage conditions (temperature and dilution), and dose.

In this phase of the project, several commercially available on-site hypochlorite generators and feed systems were also evaluated. The Project Team collected and analyzed brine streams prior to electrolytic conversion for perchlorate, chloride, metals, and other water quality constituents that may impact hypochlorite degradation and perchlorate formation. Additionally, water from the participating utilities (that also supplied hypochlorite solutions for perchlorate analysis) was used to conduct simulated distribution system (SDS) tests to determine if perchlorate would be formed in the distribution system. Actual samples from the distribution systems of participating utilities were also analyzed for perchlorate. Distribution system samples included locations having maximum chlorine contact time.

Task 4: Recommendations and Final Report

The conclusions from this research study will hopefully provide the water industry with the information needed to minimize perchlorate formation in hypochlorite solutions. Dissemination of the findings from this study include presentations and industry conferences, publication in peer-reviewed journals, and this Final Report. A complete list of recommendations for utilities using bulk hypochlorite or OSG hypochlorite can be found in the Executive Summary and in Chapter 6.

CHAPTER 2
ANALYTICAL METHODS

BACKGROUND

One of the most crucial components underlying the successful completion of this project was the validation of analytical methods for applicability in the broad array of matrices under investigation. Method validation was necessary to ensure that any empirical observations made during the course of the project could be related to precise and accurate concentrations of contaminants (within +/- 5%) in any given matrix, from 13% hypochlorite to 1% on-site generated (OSG) hypochlorite to distribution system samples with 1 ppm chlorine residual or less. Multiple analytes were identified in the initial stages of this study that had potential roles in the formation of perchlorate including transition metals (e.g., Mn, Fe, Co, Ni, and Cu), hypochlorite, chlorite, chlorate, perchlorate, bromide, and bromate. While the role of individual analytes in perchlorate (and bromate) formation could be hypothesized, good quantitation was key to the successful determination of a detailed chemical rate law. Some of the challenges in analyzing for each of the contaminants of concern included:

- Working with concentration ranges from g/L levels in concentrated hypochlorite solutions to low μg/L levels in distribution system samples, resulting in massive dilution factors (and associated error) in some cases
- High levels of hypochlorite and other salts which could potentially damage the analytical instruments
- High levels of chloride in the hypochlorite solution which can overload the liquid chromatography (LC) column and mask the presence of other analytes
- Detection of low levels of transition metals in hypochlorite solutions and distribution system samples
- Selection of a quenching agent for hypochlorite that would not contaminate or interfere with the analysis of any of the analytes of concern in the various samples collected at the SNWA laboratory or hundreds of miles away at each of the participating utility sites.

Given each of the concerns listed above, the approach for method development involved multiple steps, several of which were performed simultaneously. For the purpose of this report, however, the method development and application are listed in the most logical order for interpretation of data within the report and for future use: sample handling techniques, an overview of LC-tandem mass spectrometry (LC-MS/MS) and titrimetric methods, comparison of the methods (titration methods for use in concentrated hypochlorite solutions and LC-MS/MS for OSG and water samples), selection of a quenching agent, and metal ion quantification in hypochlorite solutions and water. For ease of use, a flow-chart summarizing the method decision making process is shown in Figure 2.1.

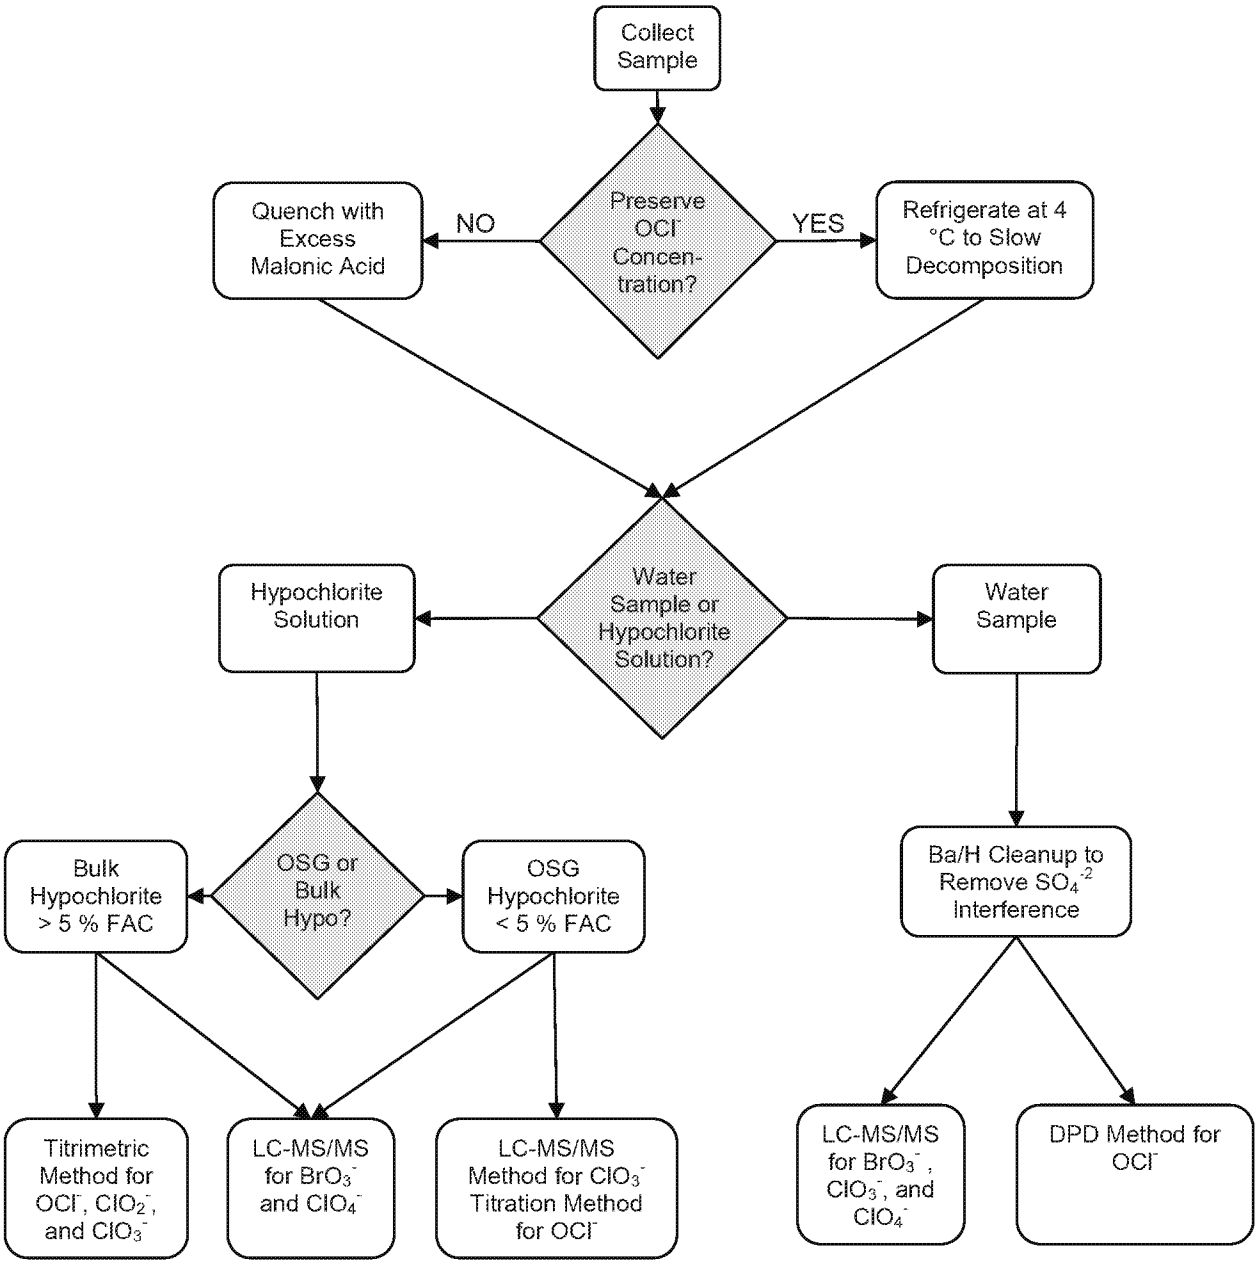

Figure 2.1 Decision tree for sample processing and analysis depending upon the type of information required and the type of sample being collected

ANALYTICAL METHODS

Sample Collection and Handling

Sodium Hypochlorite Samples

As sodium hypochlorite solutions decompose over time, thereby producing more perchlorate, controlled storage of the samples was preferred. Thus, two choices were available for this study: either quench the hypochlorite to stop subsequent formation and/or decomposition reactions or cool the samples to 4 °C to slow reaction rates significantly below those observed at room temperature. Quenching ensures the most accurate measurements of perchlorate, chlorate, and bromate when a time-of-sampling measurement is desired. Storing samples at 4 °C preserves hypochlorite (which is important for rate determination and modeling) and decreases the loss of hypochlorite significantly, thereby allowing the sample to be analyzed for hypochlorite in addition to chlorate, perchlorate, and bromate. Furthermore, unquenched samples can be used for holding studies to examine rates of formation of contaminants. For this study, duplicate samples were collected in acid-washed high-density polyethylene (HDPE) bottles and split: one sample was preserved with malonic acid while the other was cooled to 4 °C and prepared for shipment on ice to the SNWA laboratory. The reaction between hypochlorite and malonic acid is mild and slow (many minutes) and no special handling was required. However, one hour of reaction time was allowed to ensure complete quenching of hypochlorite. Malonic acid was used to quench hypochlorite in a 0.75:1 mol ratio, or approximately 11 g malonic acid for every 10 g FAC expected.

Water Samples

Water samples were collected using 125 mL, acid-washed HDPE bottles that were pre-dosed with 13 µL of a 1 M malonic acid stock solution for quenching up to 10 mg/L residual hypochlorite. Sample bottles were filled, capped, and stored at 4 °C to minimize evaporation. The perchlorate anion is very stable and does not precipitate easily, thus no pH adjustments were necessary. Once collected, the water samples were sequentially passed through one OnGuard II Ba and one OnGuard II H Cartridge (Dionex, Sunnyvale, CA) to reduce sulfate and carbonate ion concentrations. These anions have been previously shown to suppress oxyhalide concentrations when using LC-MS/MS for analysis (Snyder, Vanderford, and Rexing 2005). Care was also taken to assess the necessary cartridge capacity, as water samples have varying sulfate and carbonate ion concentrations depending on their geological background. Samples also were filtered using 0.2 µm surfactant free cellulose acetate filters (Fisher Scientific, Pittsburg, PA) to remove any suspended particulates.

LC-MS/MS Method for Bromate, Chlorate, and Perchlorate Analysis

EPA 314.0, which relies on ion chromatography (IC) coupled with conductivity detection, has long been used for the analysis of perchlorate in water. Conductivity detection is inherently a non-selective technique, as many components in aqueous mixtures are conductive, and, as a result, this method has been shown to produce false positives, where perchlorate is incorrectly identified (Johnson, Grimshaw, and Richman 2003; Mathew, Gandhi, and Hedrick 2005). This has led to the development of mass spectrometric methods for the detection and quantification of perchlorate and other oxyhalides in water (Handy, et al. 2000; Koester, Beller,

and Halden 2000; Magnuson, Urbansky, and Kelty 2000; Magnuson, Urbansky, and Kelty 2000; Richardson 2002; Roehl, et al. 2002; Rickman 2003; Gandhi, Johnson, and Joe 2004; Winkler, Minteer, and Willey 2004; Zwiener and Frimmel 2004; Snyder, Vanderford, and Rexing 2005), as these methods have been shown to be much more selective and sensitive than IC-conductivity detection. In addition, the EPA has recently released two methods for the measurement of perchlorate in water, EPA 331 and 332, using LC-MS and IC-MS, respectively (USEPA 2005a; USEPA 2005b). However, due to the unique challenges being posed by the matrices of interest, this project required a method that has been proven to be reliable in very complex matrices.

In 2005, an LC-MS/MS method developed by Snyder, et al., was published that demonstrated the reliable analysis of perchlorate in water (Snyder, Vanderford, and Rexing 2005). This method was also shown to be capable of detecting perchlorate in challenging matrices such as commercial detergents and was later adapted to measure perchlorate in aqueous extracts of vitamins and food supplements (Snyder, et al. 2006). In addition, it allowed the simultaneous identification and quantification of bromate and chlorate. Therefore, it was selected as the basis for the method used in this project to measure low level concentrations of oxyhalide anions in water and OSG samples.

Although the method discussed above was based on the work by Snyder, et al., some modifications were made. Analytes were separated using a 75 x 4.6 mm Synergi Max-RP C12 column with a 4 µm pore size (Phenomenex, Torrance, CA). A binary gradient consisting of 0.1% formic acid (v/v) in water (A) and 100% methanol (B) at a flow rate of 700 µl/min was used. The gradient was as follows: 2% B held for one minute, increased linearly to 15% B by two minutes, changed to 95% B and held for four minutes, and finally changed to 2% B and held for 3 minutes. A one minute equilibration step at 2% B was used at the beginning of each run to bring the total run time per sample to 10 minutes. An injection volume of 20 µl was used for all samples.

Tandem mass spectrometry was performed using a triple-quadrupole mass spectrometer equipped with an electrospray ionization source operated in negative ion mode (Applied Biosystems, Foster City, CA). In tandem mass spectrometry, a target analyte is first ionized in the ionization source and selected for the first quadrupole. Subsequently, the precursor ion is fragmented in the second quadrupole and a representative fragment (product ion) of the precursor is selected for in the third quadrupole. The monitoring of this transition from precursor to product ion makes the mass spectrometer very selective and sensitive. For this method, the following precursor/product ion transitions were used: $^{35}ClO_4^-$ (*m/z* 99) to $^{35}ClO_3^-$(*m/z* 83) for perchlorate; $^{35}ClO_3^-$ (*m/z* 83) to $^{35}ClO_2^-$ (*m/z* 67) for chlorate; and $^{79}BrO_3^-$ (*m/z* 127) to $^{79}BrO_2^-$ (*m/z* 111) for bromate.

To ensure the proper identification of the oxyhalides, additional ion transitions of perchlorate, chlorate and bromate using naturally occurring, stable isotopes of chlorine and bromine (chlorine-37 and bromine-81) were simultaneously monitored for purposes of confirmation. The following confirmation transitions were used: $^{37}ClO_4^-$ (*m/z* 101) to $^{37}ClO_3^-$ (*m/z* 85) for perchlorate; $^{37}ClO_3^-$ (*m/z* 85) to $^{37}ClO_2^-$ (*m/z* 69) for chlorate; and $^{81}BrO_3^-$ (*m/z* 129) to $^{81}BrO_2^-$ (*m/z* 113) for bromate.

In addition, perchlorate and bromate were quantified using the isotope dilution technique. In isotope dilution, a non-radioactively labeled analog of each target compound is added to every sample and the recovery of the labeled compound is used to determine the degree of matrix interference in the sample for each target analyte (Vanderford and Snyder 2006). Because the labeled compound behaves very similarly to the unlabeled target compound, the recovery can

then be used to correct for matrix interferences. For this project, labeled versions of perchlorate ($^{35}Cl^{18}O_4$) and bromate ($^{79}Br^{18}O_4$) were used that contain oxygen-18, a stable isotope of oxygen that occurs at only 0.20% in nature. As no source of oxygen-18 labeled chlorate was commercially available, it was quantified using external calibration.

Based on published results and other preliminary tests in our laboratory, the method reporting limits (MRL) for each matrix were determined and are shown in Table 2.1. (Note: The concentrated hypochlorite solution detection limits are based on a standard dilution factor of 1:100, though MRLs may be adjusted upwards for increased sample dilution.)

Table 2.1
LC-MS/MS MRLs (µg/L) for target analytes in water and hypochlorite solution

	Water	Hypochlorite solution
Perchlorate	0.05	5.0
Bromate	0.1	10
Chlorate	0.1	10

Titration Method for Hypochlorite, Chlorite, and Chlorate Analysis

While the LC-MS/MS method was validated and shown to be appropriate for use in water samples and in dilute hypochlorite solutions (i.e., OSG hypochlorite), a titrimetric technique was employed to measure oxychloride anions in bulk hypochlorite solutions. The titration technique used for this study was based in part on an older iodometric technique for chlorate determination (Equations 2.1, 2.2, and 2.3). This technique relies upon the fact that hypochlorite, chlorite, and chlorate ions react with iodide ion to produce iodine. This allows determination of chlorate but the technique is unable to differentiate chlorite and hypochlorite. The determination is based upon a proportional amount of iodine reacting with the analyte (shown below) followed by addition of excess concentrated hydrochloric acid to affect a color change, after which chlorate can then be titrated.

$$OCl^- + 3I^- + 2H^+ \rightarrow I_3^- + Cl^- + H_2O \quad \text{pH 1.3} \quad \textbf{(2.1)}$$

$$ClO_2^- + 6I^- + 4H^+ \rightarrow 2I_3^- + Cl^- + 2H_2O \quad \text{pH 1.3} \quad \textbf{(2.2)}$$

$$ClO_3^- + 9I^- + 6H^+ \rightarrow 3I_3^- + Cl^- + 6H_2O \quad \text{6M } H^+ \quad \textbf{(2.3)}$$

A well established way to make a standard solution of triiodide is to add a known amount of iodate to an acidic solution containing a small excess of iodide:

$$IO_3^- + 8I^- + 6H^+ \leftrightarrow 3I_3^- + 3H_2O \quad \textbf{(2.4)}$$

The prepared standard solution of I_3^- can then be used to standardize thiosulfate and sulfite solutions:

$$I_3^- + 2S_2O_3^{2-} \rightarrow 3I^- + S_4O_6^{2-} \quad \textbf{(2.5)}$$

$$I_3^- + SO_3^{2-} + 2OH^- \rightarrow SO_4^{2-} + 3I^- + H_2O \quad \textbf{(2.6)}$$

Many variations of iodometric titration methods have been developed over the years. However, potentiometric titration of hypochlorite with sulfite allows selective determination of hypochlorite ion from chlorite ion (Gordon, et al. 1993; Adam 1994). This potentiometric titration technique was used and validated in previous work to study the decomposition of hypochlorite and the subsequent formation of chlorite and chlorate in concentrated hypochlorite solutions (Gordon, et al. 1993; Adam 1994; Adam and Gordon 1995; Gordon, et al. 1997). Given the previous validation and expertise within the Project Team, the potentiometric method was used for analysis of oxychloride anions in concentrated hypochlorite solutions. The sequential determinations of specific anions were carried out in five sequential steps as outlined in Equations 2.7 – 2.11:

Step 1: Titration of OCl^- at pH 10.5:

$$OCl^- + SO_3^{2-} \rightarrow SO_4^{2-} + Cl^- \quad \textbf{(2.7)}$$

Step 2: Removal of excess SO_3^{2-} at pH 10.0 – 10.5:

$$I_3^- + SO_3^{2-} + 2OH^- \rightarrow SO_4^{2-} + 3I^- + H_2O \quad \textbf{(2.8)}$$

Step 3: Removal of excess I_3^- at pH 9 – 10.5:

$$I_3^- + 2S_2O_3^{2-} \rightarrow 3I^- + S_4O_6^{2-} \quad \textbf{(2.9)}$$

Step 4: Determination of ClO^{2-} at pH 1.3:

$$ClO_2^- + 6I^- + 4H^+ \rightarrow 2I_3^- + Cl^- + 2H_2O \quad \textbf{(2.10)}$$

Step 5: Determination of ClO_3^- after addition of concentrated HCl :

$$ClO_3^- + 9I^- + 6H^+ \rightarrow 3I_3^- + Cl^- + 3H_2O \qquad 6M\ H^+ \quad \textbf{(2.11)}$$

Titrations with sulfite were carried out using a VIT 90 Video Titrator with a P101 platinum k401 SCE electrode pair (Radiometer, Copenhagen, Denmark). Titrations with thiosulfate were performed with a standard 50 mL laboratory glass burette. Concentrated hydrochloric acid (ACS reagent grade, Fisher Scientific, Pittsburg, PA) and the sample solution were purged with nitrogen gas to minimize oxidation of iodide by oxygen prior to chlorate determination. Potassium iodate standard (0.1 M) was prepared weekly using high purity (>99.4%) potassium iodate and used to standardize sulfite and thiosulfate solutions daily. Standardization by this method resulted in standard deviations of less than three parts per thousand and less than 1% relative standard deviation. The 0.2 M SO_3^{2-} solutions were prepared from ACS reagent grade sodium sulfite. The 0.1 M $S_2O_3^{2-}$ solutions were prepared from ACS reagent grade sodium thiosulfate.

ICP-MS Method for Metals Analysis in Sodium Hypochlorite Solutions

Metal ion analysis and quantification was carried out using US EPA method 200.8 on an Agilent (Palo Alto, CA) 7500c Inductively Coupled Plasma-Mass Spectrometer (ICP-MS) with an Octopole Reaction System that uses hydrogen-helium reaction gas to remove Ar-based isobaric and polyatomic oxide interferences. Internal standards were used to correct for matrix interferences. Dilutions ranging from 1:10 to 1:500 were used to reduce the impact of the high total dissolved solids (TDS) background of hypochlorite samples. Actual MRLs are summarized in Table 2.2.

Table 2.2
ICP-MS method reporting limits (µg/L) in water and hypochlorite solutions

Metal	Water*	Hypochlorite solution*
Manganese (Mn)	1.0	25
Iron (Fe)	5.0	125
Cobolt (Co)	2.0	25
Copper (Cu)	5.0	25
Nickel (Ni)	1.0	25

*Occasionally higher MRLs are shown in the text when higher dilution factors were used; the MRLs listed are the lowest level at which data are reported in the text of this report; The proportionality of MRLs between water and hypochlorite varied based on required dilution factors

Specific Conductance, Ionic Strength, and pH Measurements

Specific conductance measurements were performed using a HACH Ion-Series Conductivity/Total Dissolved Solids meter (Hach Company, Loveland, CO). A calibration was performed using a 1,000 µmho/cm standard prior to sample analysis. In most cases dilutions were required to bring the conductivity to within the linear range of the probe. Specific conductance was measured in order to determine the ionic strength of hypochlorite solutions. Ionic strength (I) was calculated from specific conductance (σ) using Equation 2.12:

$$I\ (mol/L) = 1.6 \times 10^{-5} \times \sigma\ (\mu mho/cm) \qquad \textbf{(2.12)}$$

Total dissolved solids (TDS) could also be approximated by Equation 2.13:

$$TDS\ (mg/L) \sim I * 4 \times 10^{4} \qquad \textbf{(2.13)}$$

An AP62 pH/mV Meter (Fisher Scientific, Pittsburg, PA) was used to measure sample pH. Meter calibrations using standard pH buffers (pH 4, 7, 10) was performed prior to measurements of samples.

Quality Assurance and Quality Control

Quality assurance and quality control followed EPA Method 331 for LC-MS/MS analysis and EPA Method 200.8 for metals analysis. Significant time was devoted to validate the use of the quenching agent of choice (malonic acid) and to validate the methods for applicability to each matrix (e.g., LC-MS/MS for OSG and water, titrations for bulk hypochlorite). Validation was performed using matrix spikes, blanks, and split samples for comparison.

METHOD VALIDATION

Selection of Quenching Agent

The selection of a hypochlorite quenching agent was critical for the monitoring component of this project and for experiments that were conducted off-site at a manufacturing facility. Some initial concern was raised about the potential negative impact of unquenched hypochlorite ions on the mass spectrometer, though this turned out not to be a factor and thus was not a major component in the decision making process. For any experiments performed on-site where chemical reactions/reaction rates needed to be stopped or attenuated, simply refrigerating the sample aliquots at 4 °C significantly slowed the reaction: the half life of 13% NaOCl solution at 25 °C is 130 days, at 4 °C the half life is 3184 days, according to the Bleach 2001 Predictive Model (Adam, Gordon, and Pierce 2001). Thus, temporary storage of concentrated hypochlorite samples at 4 °C (for up to several weeks) still allowed accurate determinations of hypochlorite and perchlorate concentrations. However, in cases where precise temperature control was not possible or was in question, the use of a quenching agent was necessary for the quantification of other ionic species present in the hypochlorite solutions or water sample.

A total of seven hypochlorite quenching agents were investigated for use in this project based on descriptions in the literature (Gordon 1990; Wood 1990; Sweetin 1993; Adam 1995; Liu 2003) and from current practices at the SNWA laboratory. The quenching agents tested included ascorbic acid, malonic acid, oxalic acid, glycine, sodium sulfite, sodium thiosulfate, and hydrogen peroxide. The selection of the final quenching agent was based on the following criteria:

- Safety, ease of handling, transport, and stability
- Ability to quench hypochlorite reproducibly
- No appreciable impact on bromate levels
- No appreciable impact on chlorate levels
- No appreciable impact on perchlorate levels
- Amount of transition metals present in appreciable concentration to impact analysis (i.e., contamination)
- Number of moles required and cost
- Compatibility with iodometric determination (i.e., quenching agent does not react with iodide or interfere with titration method)

Safety, Ease of Handling, Transport, and Stability

Several of the quenching agents under consideration (hydrogen peroxide, glycine, and oxalic acid) reacted vigorously with hypochlorite, causing significant loss of sample during the reaction, and/or produced heat and noxious fumes. Concentrated solutions of hydrogen peroxide (32% w/w) require special handling and quenching 10 mL of 13% sodium hypochlorite solution produced a considerable amount of heat and gas, making this quenching agent the most dangerous to use. Glycine, though relatively safe itself, reacted violently and produced a very noxious gas when reacted with hypochlorite that can potentially cause light-headedness, dizziness, and nausea. The remaining quenching agents also produced heat and gas, but to a lesser extent. Ascorbic acid reacted the least vigorously and appears to be the safest quenching agent tested. None of the quenching agents had associated transportation restrictions (other than including MSDS information with each shipping carton) with the exception of concentrated hydrogen peroxide.

Regarding stability, hydrogen peroxide and sodium sulfite in solution have limited stability and limited shelf-lives. In solution, sodium sulfite may decay by as much as 1% per hour (Adam and Gordon 1995) but may be more stable if used as a solid salt. Ascorbic acid produced marked color changes that can interfere with titrimetric analyses, both during storage of a 1 M stock solution (Figure 2.2) and after quenching of utility hypochlorite samples. Stock solution color change ranged from a colorless solution upon first preparation, to a yellow solution after 20 days of storage at 4 °C, to a dark red solution after 37 days of storage at 4 °C. Quenched hypochlorite solutions exhibited similar color changes due to presence of excess ascorbic acid (Figure 2.3). The development of color in quenched concentrated hypochlorite samples would interfere with the determination of chlorate ion concentration because the iodometric titration has a colorless end-point.

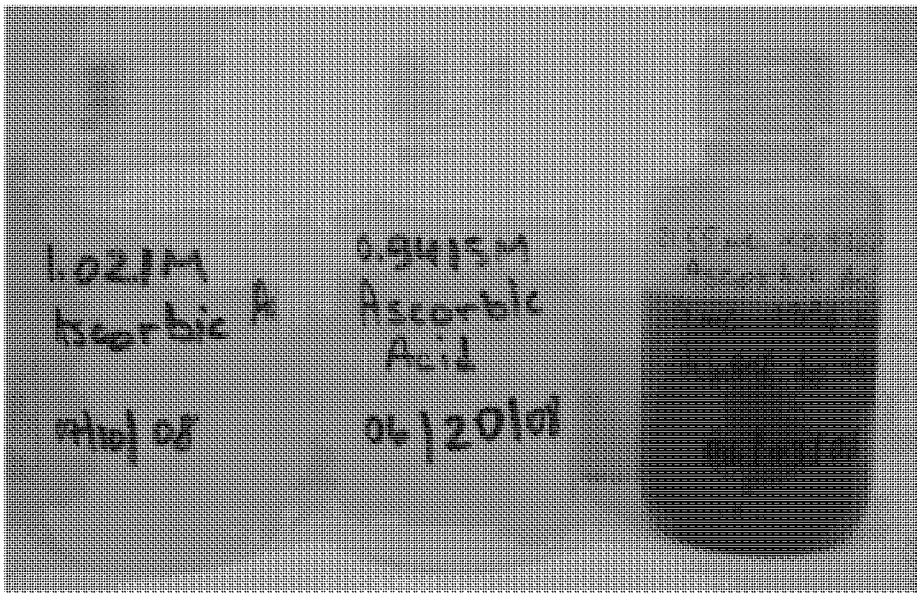

Figure 2.2 Stock solutions of ascorbic acid at t = zero (left), t = 20 days old (center), and t = 37 days old (right)

Figure 2.3 Quenched hypochlorite samples from utilities using ascorbic acid (left 3 bottles) and malonic acid (right bottle)

Ability to Quench Hypochlorite Reproducibly

All quenching agents tested were able to quench hypochlorite in test samples. Ascorbic acid, malonic acid, and oxalic acid were able to quench hypochlorite in different concentration and volume solutions of hypochlorite. The mole ratio of quenching agent to hypochlorite (OCl^-) was 1.2 for ascorbic acid, 0.75 for malonic acid, and 1.5 for oxalic acid. Glycine was the least reproducible quenching agent with mole ratios varying from 0.20 to 0.53; one hypothesis is that the reaction is temperature, pH, and mixing dependent and thus may produce variable results depending on sample composition and handling. Oxalic and malonic acids were the slowest reactants, requiring up to one hour for complete quenching of 13% hypochlorite solution. Sodium thiosulfate and sodium sulfite were found to quench hypochlorite reproducibly, though the sodium sulfite had to be standardized prior to use in order to determine the volume required to deliver the appropriate moles of quenching agent.

Impact on Bromate, Chlorate, and Perchlorate Measurements

In early experiments, sodium thiosulfate and sodium sulfite were observed to have an effect on the analysis of bromate by LC-MS/MS. Both bromate and the internal standard were negatively impacted by the presence of thiosulfate and sulfite. Chromatograms of the non-quenched, sulfite-quenched, and thiosulfate-quenched, 13% sodium hypochlorite samples are shown in Figures 2.4 – 2.6. The chromatograms of a non-quenched sample (Figure 2.4) versus sulfite- (Figure 2.5) and thiosulfate- (Figure 2.6) quenched samples illustrate the observed effects on LC-MS/MS analysis of bromate. In Figure 2.4, the internal standard peak height is around 300 counts (retention time 2.04 min) and effectively corrects for matrix effects, with observed average recoveries in spiked samples (n=3) at 91%. For samples quenched using sulfite and thiosulfate, peak shifts, peak attenuation (Figures 2.5, 2.6), and peak splitting (Figure 2.5) were observed. Furthermore, severe matrix suppression of both analyte and internal standard signals hindered the ability for adequate correction, yielding poor recoveries for samples quenched with thiosulfate (60%, n = 3) and no quantifiable recoveries for samples quenched with sulfite. Ascorbic acid also negatively impacted analysis of bromate. When hypochlorite solutions, quenched with ascorbic acid were analyzed, no detectible concentration of bromate was observed. Furthermore, spiked ascorbic acid-quenched hypochlorite solutions with bromate standard, showed much lower recoveries (49%, n=3) than the non-quenched hypochlorite solutions, indicating that excess ascorbic acid in fact may reduce bromate concentration (shown in Table 2.3). The observation of sulfite, thiosulfate, and ascorbic acid reduction of bromate is similar to that made by Keith *et al.* (2006) where sulfite was similarly shown to reduce bromate in gastric juices. The remaining quenching agent (malonic acid) was shown to have no impact on bromate analysis. Recovery data obtained by LC-MS/MS analysis of dilute hypochlorite samples for the remaining quenching agents are shown in Table 2.3.

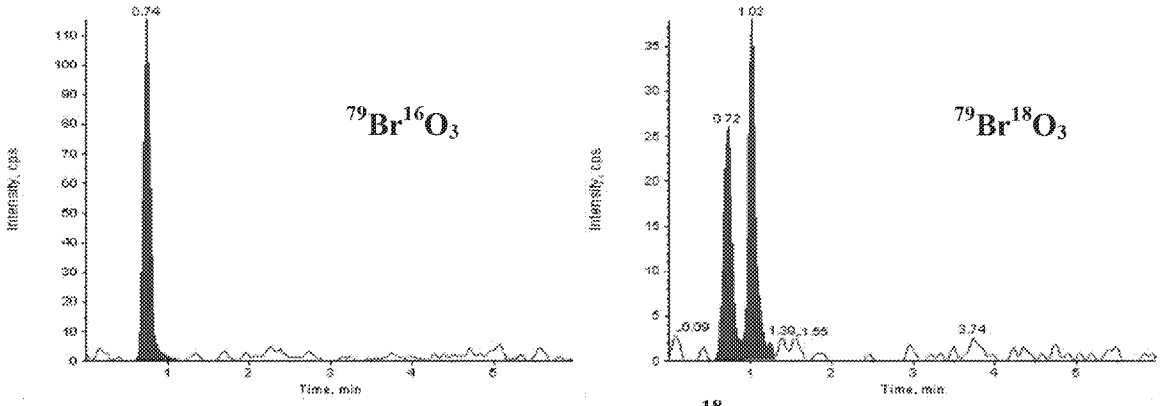

Figure 2.5 Chromatogram of bromate (left) and ^{18}O-labeled bromate (right) of a sulfite-quenched sample of 13% sodium hypochlorite solution diluted by a factor of 1:10,000

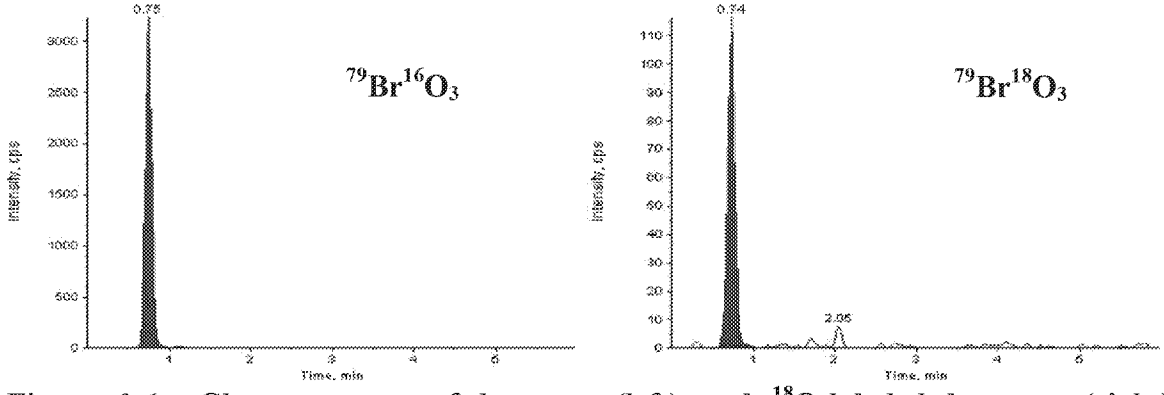

Figure 2.6 Chromatogram of bromate (left) and ^{18}O-labeled bromate (right) of a thiosulfate-quenched sample of 13% sodium hypochlorite solution diluted by a factor of 1:10,000

Table 2.3
Effects of quenching agent on analysis of chlorate, perchlorate, and bromate (n=3)

LC-MS/MS results	Non-quenched hypochlorite	Ascorbic acid	Malonic acid
Chlorate, g/L	16.1 ± 0.15	14.1 ± 0.25	15.7 ± 0.15
Chlorate recovery (matrix spike)	90.8 ± 4	96.2 ± 3	88.9 ± 0.5
Perchlorate mg/L	7.41 ± 0.10	7.42 ± 0.9	7.12 ± 0.5
Perchlorate recovery (matrix spike)	101 ± 1.8	107+1.7	104 ± 2.3
Bromate, mg/L	16.01 ± 0.25	Non-Detect	14.80 ± 0.09
Bromate recovery (matrix spike)	94.3 ± 6.5	*48.6 ± 2.2	96.7 ± 1.1

*Value based on bromate spike in non-quenched hypochlorite sample.
This indicates excess ascorbic acid may reduce bromate concentration.

Number of Moles Required and Cost

Several quenching experiments were performed in order to determine the stoichiometric amounts of quenching agent to hypochlorite required. Experiments were carried out in 13% hypochlorite and residual chlorine was measured using the DPD test. Sodium thiosulfate required the least number of moles to quench hypochlorite and was the most cost effective quenching agent ($0.11 per 10 mL of 13% hypochlorite). However due to potential interferences with the bromate analysis, sodium thiosulfate was removed from further consideration. Thus, malonic and oxalic acids remained as quenching agent candidates. Out of these two, malonic acid was the most cost-effective and required a smaller number of moles to quench sodium hypochlorite. Though costs were considered in this study for reference, it was not a major factor in the final choice of quenching agent.

Quenching Agent Decision Matrix

A generalized decision matrix is included in Table 2.4 with bold-faced text referring to reasons for rejecting a given quenching agent. Based on safety, ease of handling, transport, and stability, *glycine, hydrogen peroxide, sodium sulfite, and ascorbic acid were not recommended for quenching.* Based on negative impacts on bromate analysis, *ascorbic acid, sodium thiosulfate was not recommended for quenching.* Based on limited solubility of oxalic acid in bulk sodium hypochlorite solutions, *oxalic acid was not recommended for quenching.* Thus, malonic acid was chosen as the quenching agent of choice for experiments requiring preservation (typically for samples collected off-site and requiring shipping). For in-house experiments, the use of quenching agent was not required as the mass spectrometric and the titrimetric methods were not impacted by residual FAC; cooling the samples to 4 °C was sufficient to slow the reactions below appreciable levels if analyzed within a 3-month window.

Table 2.4
Summary of quenching agent test results and decision-making matrix

	Quenching Agent (QA)						
	Ascorbic Acid	Glycine	Malonic Acid	Sodium Thiosulfate	Sodium Sulfite	Oxalic Acid	Hydrogen Peroxide
Stoichiometric ratio of quenching agent to FAC*	1.2	0.55	0.75	0.28	1.1	1.5	1.1

Soluble in hypochlorite solutions?	Yes	Yes	Yes	Yes	Yes	**No**	Yes

*FAC = Free available chlorine as measured by DPD method; Bold-faced type represents reason for rejecting a g quenching agent

Validation of LC-MS/MS Method for the Analysis of Hypochlorite Solutions

Sodium hypochlorite solutions subjected for analysis ranged from 0.35 – 13%. Thus, a robust sample preparation method had to be identified in order to ensure accurate and reproducible detection of bromate, chlorate, and perchlorate. Furthermore, sulfate, known to occur in natural water, posed a potential source of isobaric interference to the analysis of perchlorate; as such, sulfate removal techniques (e.g., barium/hydrogen cartridge filters) were used initially on unknown (i.e., utility) samples until it could be determined by analysis of an unfiltered sample that no sulfate interference existed.

Analysis of hypochlorite and hypochlorite plus chlorate, bromate, and perchlorate spikes with and without sulfate removal steps were compared to validate the clean-up steps. Sample solutions were passed sequentially through one 2.5cc OnGuard II Ba and one 2.5cc OnGuard II H Cartridge (Dionex, Sunnyvale, CA) to reduce sulfate and carbonate ion concentrations. The cartridges were conditioned by flushing and discarding 30 mL deionized water. Sample solutions were eluted typically at a flow rate of 2.0 mL/min using mechanical syringe pump and at least the first 10 mL of eluent were discarded prior to collecting a sample aliquot for analysis. The results of dilutions on measured analyte concentration with and without the clean-up step are summarized in Tables 2.5 and 2.6. There were no major differences between filtered and unfiltered samples observed that could not be explained by the dilution effects discussed below. Thus, it was decided that if sulfate interference was possible, the use of a clean-up/filtration step with Barium cartridges would not negatively impact analysis.

Table 2.5
Measured analyte concentrations with and without filtration and at different dilutions (n = 3)

		ClO_3^- (mg/L)				BrO_3^- (µg/L)				ClO_4^- (µg/L)		
	Dilution factor	5000	1000	100	10	5000	1000	100	10	1000	100	10

	Std. Dev.	10.2	25.6	10.7	5.9	6.8	3.5	40.8	3.5	2.3	3.9
	RSD	10.5	11.3	132.3	6	7.5	4	250.4	3.3	2.3	3.9

In addition to the clean-up and filtration tests, a series of dilution tests were also completed in order to examine the impact of other matrix interferences (e.g., ion suppression, ion enhancement, isobaric interferences, chromatographic resolution). The analysis of perchlorate was the least impacted by sample dilution with matrix recoveries hovering around 100% for all dilutions and analyte concentrations remaining within 3% regardless of dilution factor. Thus, perchlorate analysis was able to be performed at dilutions as low as 1:10, achieving a lower MRL than originally proposed. Chlorate was typically present at levels approaching the g/L range, requiring dilutions of several orders of magnitude. Analysis of bromate was the most susceptible to the matrix effects. Interestingly, the loss in signal of the ^{18}O-labeled bromate was much higher than that of the analyte at 1:10 and 1:100 dilutions. At a 1:1000 dilution, peak-widening was significantly reduced and showed no effect on the accuracy. Examples of the chromatograms of bromate ion signal are shown in Figures 2.7 – 2.9. At a 1:100 dilution, however, the bromate peak appears to be reasonably resolved, yet the ^{18}O-labeled bromate internal standard peak is significantly impacted by matrix interferences, thereby producing an erroneous result. A higher dilution eliminated this problem. In most cases, the sensitivity of the LC-MS/MS method allowed matrix effects to be minimized by diluting the samples. Fig. 2.10 illustrates the improvement in accuracy of the analytes based on the dilution factor.

Comparison of LC-MS/MS and Titrimetric Methods: Selection Criteria for Sample Analysis

Sodium hypochlorite solutions are provided as either bulk, which is commercially available 6.5-13% as Free Available Chlorine (FAC), or as On-site Generated NaOCl that typically is 0.3-3% as FAC. Concentration of chlorate in some bulk hypochlorite samples was present at 200 g/L, thus dilutions on the order of 1:1,000,000 were needed for the LC-MS/MS analysis. In OSG hypochlorite, chlorate concentrations were typically below 1 g/L, which proved difficult to measure by iodometric titration. To determine which method (iodometric titration or LC-MS/MS) was best for chlorate analysis of either bulk or OSG sodium hypochlorite solutions, replicate samples were split and analyzed by both methods and their results compared. A comparison of the two methods for analysis of seven replicate bulk hypochlorite solutions is shown in Table 2.7.

Table 2.7
Data from the analysis of 7 replicate bulk hypochlorite solutions (13 % FAC) by LC-MS/MS and titration methods

	Unspiked hypochlorite		ClO_3^- spiked hypochlorite		% Recovery	
Replicate	LC-MS/MS	Titration	LC-MS/MS	Titration	LC-MS/MS	Titration
1	16.9	17.7	24.4	25.2	95.7	95.1
2	18.0	17.9	24.4	24.8	81.7	88.3
3	15.9	17.7	23.5	25.2	97.0	95.1
4	15.4	17.7	23.1	25.0	98.3	92.8
5	16.1	17.9	25.1	25.2	115	92.8
6	12.9	17.9	24.0	25.2	142	92.8
7	16.5	18.1	23.0	25.4	83.0	92.8
Mean	**16.0**	**17.9**	**23.9**	**25.1**	**102**	**92.8**
Std. Dev.	1.6	0.1	0.8	0.2	20.8	2.3
RSD	**9.9**	**0.8**	**3.2**	**0.7**	**20.4**	**2.4**

These results indicate that, although both methods produce similar results, titration of the concentrated hypochlorite solutions resulted in much lower relative standard deviations (RSD) than the LC-MS/MS method. The higher variability observed in the LC-MS/MS results are most likely a result of the number of dilutions in order to bring 10 – 200g/L concentrations down to the calibration curve of 5 – 500 µg/L or a dilution factor of up to 1,000,000. Carrying out serial dilutions of several orders of magnitude may have compounded errors associated with each dilution made resulting in higher variability. This variability can be visually observed from the comparison of the results from two methods of duplicate samples during a chlorate-spike experiment, shown in Fig. 2.11. It should be noted that in this context connecting lines were used for visual impact. However, in all other figures (unless otherwise noted), best-fit lines are used.

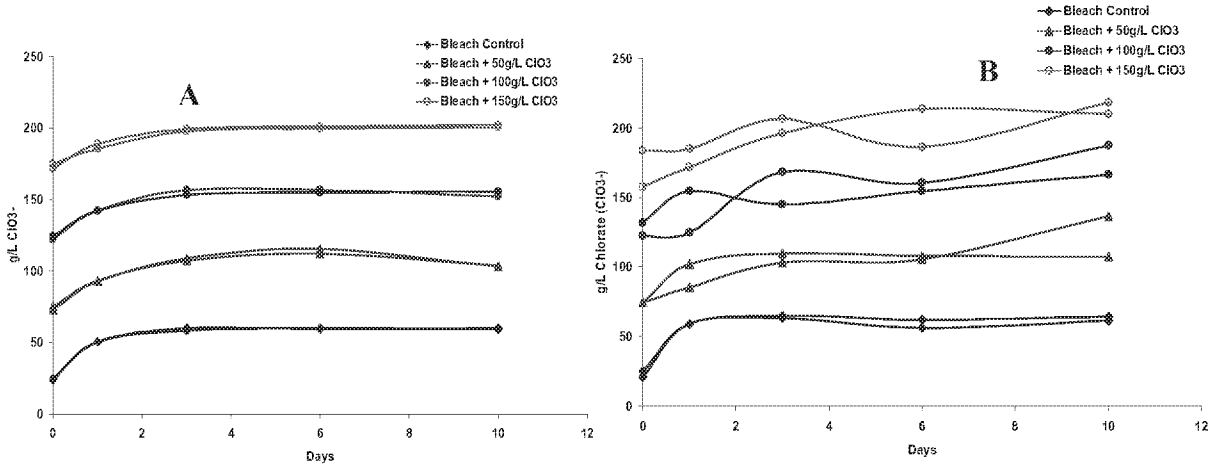

Figure 2.11 Comparison of chlorate ion concentrations measured by titration (A) and by LC-MS/MS (B) during a chlorate-spike experiment

Given these results, the iodometric titration method was used for the vast majority of bulk hypochlorite samples for the determination of chlorate ion concentration. However, for the analysis of OSG hypochlorite, the titration method could not be used as reliably. The results shown in Table 2.8 indicate poor precision for determination of chlorate at concentrations less than 1.0 g/L (10 mM).

Table 2.8
Data from the analysis of replicate OSG hypochlorite solutions with concentration of ClO_3^- at less than 1.0 g/L (< 10 mM) by iodometric titration and LC-MS/MS methods

	Titration	LC-MS/MS
Mean	**0.560**	**0.31**
Std. Dev.	0.20	0.005
RSD (%)	35.23	1.55
	(n=4)	(n=3)

Results are in g/L ClO_3^-

The iodometric determinations of chlorate concentrations at less than 1 g/L were unreliable, thus requiring analysis by LC-MS/MS. Therefore, chlorate measurements for samples from bulk hypochlorite were analyzed by iodometric titration while OSG hypochlorite solutions were analyzed by LC-MS/MS. Specifically, the iodometric titration method was used for determination of chlorate concentrations in 10 – 250 g/L range (generally in hypochlorite solutions with >5% FAC), while LC-MS/MS method was used for trace chlorate analysis in the 0.01 – 10,000 mg/L range (generally in hypochlorite solutions with <5% FAC).

CHAPTER 3
FACTORS IMPACTING PERCHLORATE FORMATION

BACKGROUND

The kinetics of the decomposition of the hypochlorite ion and subsequent formation of chlorite and chlorate ions in hypochlorite solutions has been well described and was the basis for much of the experimental design for this study (Gordon, et al. 1993; Adam 1994; Adam and Gordon 1995; Gordon, Adam, and Bubnis 1995; Gordon, et al. 1997; Adam and Gordon 1999). The results of the aforementioned research formed the underpinnings of the *Bleach 2001* predictive model (Adam, Gordon, and Pierce 2001), designed for bulk hypochlorite solutions in the pH range of 11 to 14 and for storage conditions with temperatures from 0 °C to 50 °C. The narrow pH range defined in the model is due to the fact that (1) the mechanism for hypochlorite ion decomposition is different (and the rate faster) at or below pH 10.5 and (2) most bulk hypochlorite samples used by drinking water utilities fall within the pH 11 – 14 range. The exception, of course, would be OSG hypochlorite which typically fall within the pH 9 – 10 range. The lack of applicability of the *Bleach 2001* model to OSG hypochlorite is less of a concern, however, as such solutions are typically used immediately, or at most within 48 to 72 hours of production. Thus, the work carried out for this current research study was designed around the use of bulk hypochlorite solutions in the pH 11 to 14 range in order to elucidate the mechanism of perchlorate formation.

Upon commencement of the research for this study the following facts were known about the chemistry of sodium hypochlorite solutions (Adam 1994):

1. Hypochlorite ion can decompose in the pH 11 – 14 range to form chlorate and chloride (Equation 1.1, Chapter 1) or, in the presence of a catalyst, oxygen gas and chloride (Equation 1.2, Chapter 1).

2. The rate law defining the decomposition of the hypochlorite ion in the pH 11 – 14 is defined by second order decomposition (Equation 1.3, Chapter 1).

3. The decomposition of the hypochlorite ion concomitantly results in the production of an intermediate species, the chlorite ion, which essentially remains at steady state during the production of chlorate ion.

4. The ionic strength of the hypochlorite solution impacts the rate of hypochlorite ion decomposition and subsequent chlorate ion formation; higher ionic strength favors faster reaction rates. The relationship between ionic strength, observed rate constant (k_{obs}), and the rate constant for infinite dilution (k_0, for 'zero' ionic strength) is defined by Equation 3.1.

$$\log k_{obs} = 0.149(I) + \log k_0 \qquad \textbf{(3.1)}$$

5. The pH of the hypochlorite solution impacts the rate of hypochlorite ion decomposition and chlorate ion formation; this reaction is minimized in the pH

11.86 – 13.00 region. At pH 14, the excess hydroxide ions contribute to the ionic strength, thereby also increasing the rate of reaction by a factor of 1.5 above that observed at pH 13.

6. Diluting hypochlorite solutions by a factor of two reduces the concentration of hypochlorite ion and ionic strength resulting in nearly a five-fold decrease in the rate of decomposition

7. The rate of hypochlorite ion decomposition increases proportionally with temperature and can be related to the zero ionic strength rate constant using the enthalpy ($\Delta H^{\ddagger}$) and entropy ($\Delta S^{\ddagger}$) of activation (Equation 3.2).

$$k_0 = 2.083 \times 10^{10} (T) \times e^{(-\Delta H^{\ddagger}/RT)} \times e^{(\Delta S^{\ddagger}/R)} \quad \textbf{(3.2)}$$

   By storing hypochlorite solutions at 15 °C instead of 25 °C, the rate of decomposition decreases by a factor of 3.8; Cooling from 35 °C to 15 °C decreases the rate of decomposition by a factor of 14.

8. Hypochlorite ion decomposition is not impacted by the presence of carbonate or sulfate ions.

9. The presence of some transition metal ions catalyzes the decomposition of hypochlorite ions. Fe(III) and Mn(II) were shown to have no effect at concentrations of 1.1 mg/L for Mn(II) and 42 mg/L for Fe(III). Ni(II) present at 1 mg/L was able to increase the rate constant by a factor of 10, while Cu(II) at the same concentration only increased the rate constant by a factor of 1.4. However, at 10 mg/L, Cu(II) was able to increase the rate constant by a factor of 18.

With the facts listed above in mind, several hypotheses were developed to guide the experimental design:

1. The formation of perchlorate ion is a direct result of reactions between hypochlorite and chlorate ions in the following, generalized reaction:

$$OCl^- + ClO_3^- \rightarrow ClO_4^- + Cl^- \quad \textbf{(3.3)}$$

   What was not clear, however, was the reaction order with respect to hypochlorite and chlorate ions, though it was hypothesized that the reaction would be first order in both chlorate and hypochlorite.

2. The chlorite ion, given its steady state concentration, is not likely to impact the rate of formation of perchlorate ion.

3. The presence of bromide and bromate ions will not impact the rate of formation of perchlorate ion given that bromide and bromate ions are generally present at low concentrations relative to chloride and chlorate ions.

4. Temperature and ionic strength were hypothesized to impact the rate of perchlorate ion formation in a manner analogous to that of the decomposition of hypochlorite ion and subsequent formation of chlorate ion.

5. Higher initial concentrations of hypochlorite and chlorate ions were hypothesized to increase the rate of perchlorate ion formation.

6. The role of pH is likely to be significant in perchlorate ion formation. However, given the goal of predicting perchlorate formation in bulk hypochlorite, the pH ranges suggested in the experimental design were generally in the pH 11 – 14 range.

7. The presence of transition metal ions was hypothesized to impact the rate of perchlorate ion formation, though it was unclear whether the effect would enhance or retard the rate of formation.

APPROACH

Given each of the considerations and hypotheses listed above, a series of incubation studies on commercially available sodium hypochlorite solutions were carried out in the laboratory. Two hypochlorite suppliers were used: 13% FAC from Acros Organics USA (Morris Plains, NJ) and 10–14% w/w from VWR (Brisbane, CA). Analog and digital, general-purpose, heated water baths (VWR, Brisbane, CA) were used for incubations at 30, 40, 50, 60, and 76 °C. Temperatures were monitored daily, using glass laboratory mercury thermometer or a thermocouple thermometer with an LCD screen (Fisher Scientific, Pittsburgh, PA). Potassium bromide, Certified ACS grade (Fisher Scientific, Pittsburgh, PA); sodium bromate, 99.5% min (EMD Chemicals Inc., Gibbstown, NJ); sodium chlorate, ACS Grade, ≥99% pure (VWR, Brisbane, CA); and sodium chlorite, unstabilized, Technical Grade 80% (Acros Organics USA, Morris Plains, NJ) were added to sodium hypochlorite solutions to investigate individual and combined effects of contaminants on the decomposition of hypochlorite, formation of bromate, chlorate, and perchlorate. To adjust the pH of the sodium hypochlorite solutions, sodium hydroxide (reagent grade, ≥98%, pellets, Sigma-Aldrich, St. Louis, MO) and hydrochloric acid (ACS reagent, 37%, Sigma-Aldrich, St. Louis, MO) were used. To investigate the effects of metal ions, aliquots of 1,000 ppm Co, Cu, Fe, Ni, and Mn Standards (SPEX CertiPrep®, Inc., Metuchen, NJ) and 1,000ppm Ag, Au, Ir, Pd, and Pt Standards (Elements Inc., Shasta Lake, CA) were spiked into sodium hypochlorite solutions. Dilutions of the sodium hypochlorite solutions and preparation of standards was performed using reagent water purified using Milli-Q Gradient System (Millipore, Billerica, MA). In order to investigate factors that impact perchlorate formation, over 1,600 sample titrations and 1,600 LC-MS/MS data points were collected (not including standardization titrations and calibrations).

INVESTIGATION OF FACTORS IMPACTING PERCHLORATE FORMATION

Part of the challenge faced in designing this research study was how best to design the experiments to provide the amount of information required to determine a chemical rate law within the 9 month time line. Given the short duration of the study, the decision was made that multiple factors would need to be investigated simultaneously while still ensuring that the proper

controls were in place to elucidate individual effects. Thus, at the end of the experimental phase of the study, a significant amount of deconvolution of factors/effects was required. Using the data collected from the experiments designed for this study, the individual effects of oxychloride ion concentration, bromide and bromate concentrations, metal ion concentration, ionic strength (using conductivity as a surrogate measure to calculate ionic strength), temperature, and pH were discernable. However, in presenting the results, the reader may notice some overlap between the sections and/or find questions that are raised in one section but are not fully answered until a later section. To keep this to a minimum, the factors impacting the rate of perchlorate formation are presented in the following order: hypochlorite and chlorate ion concentration effects, chlorite ion effects, metal ion effects, bromide and bromate ion effects, temperature, ionic strength, and pH.

Effects of Hypochlorite Ion and Chlorate Ion Concentrations on the Rate of Perchlorate Formation

To investigate effects of chlorate and hypochlorite ions on perchlorate formation, solutions of sodium hypochlorite were spiked with variable amounts of chlorate and hypochlorite ions and incubated at 30, 40, and 50 °C for periods of up to 200 days. The samples were divided into three unique sets and labeled as follows:

- Constant hypochlorite concentration with variable chlorate concentrations
- Constant chlorate concentrations with variable hypochlorite concentrations
- A constant mole product of [hypochlorite] x [chlorate]

The use of sodium hypochlorite solutions with constant [OCl^-] and variable [ClO_3^-] were used to elucidate the order of the rate of perchlorate formation with respect to chlorate ion. Similarly, solutions with constant [ClO_3^-] and variable [OCl^-] concentrations were used to determine the order with respect to hypochlorite. Should the results indicate that the formation of perchlorate is first order in hypochlorite and first order in chlorate, the constant mole product results would be expected to form the same amount of perchlorate over the incubation period. Given the hypothesis that the initial rate of reaction is first order in chlorate and first order in hypochlorite (thus second order overall), the following rate law equation was proposed:

$$\frac{d[ClO_4^-]}{dt} = k_2[ClO_3^-]^m[OCl^-]^n \qquad \textbf{(3.4)}$$

Where k_2 = the apparent second order rate constant and m and n are approximately 1.

Constant Hypochlorite with Variable Chlorate at 30, 40, and 50 °C

In this set of experiments, hypochlorite solutions were prepared having the same starting hypochlorite ion concentration[1], while additional chlorate ion was spiked at 50 g/L, 100 g/L, and

[1] As a point of reference for discussion, a bulk hypochlorite solution of 13% FAC equates to approximately 2 M OCl^-, 103 g/L OCl^-, 149 g/L NaOCl, and/or 13.6% NaOCl (depending on specific gravity).

150 g/L. A control solution containing no additional chlorate ion above the background was also included. All samples were incubated in duplicate. The results presented in Figures 3.1 demonstrate the effects of different initial chlorate ion concentrations on formation of perchlorate ion at 30 °C (a), at 40 °C (b), and at 50 °C (c). The results presented in Figures 3.2 demonstrate the effects of different initial chlorate ion concentrations on the decomposition of hypochlorite ion and formation of chlorate ion at 30 °C (a), at 40 °C (b), and at 50 °C (c). The addition of chlorate to the hypochlorite solution causes a proportionate increase in perchlorate, confirming that changes in initial chlorate ion concentration affect the rate of formation of perchlorate. Casual observation of the results would point toward a reaction mechanism that is first order in chlorate (this is elucidated in more detail later).

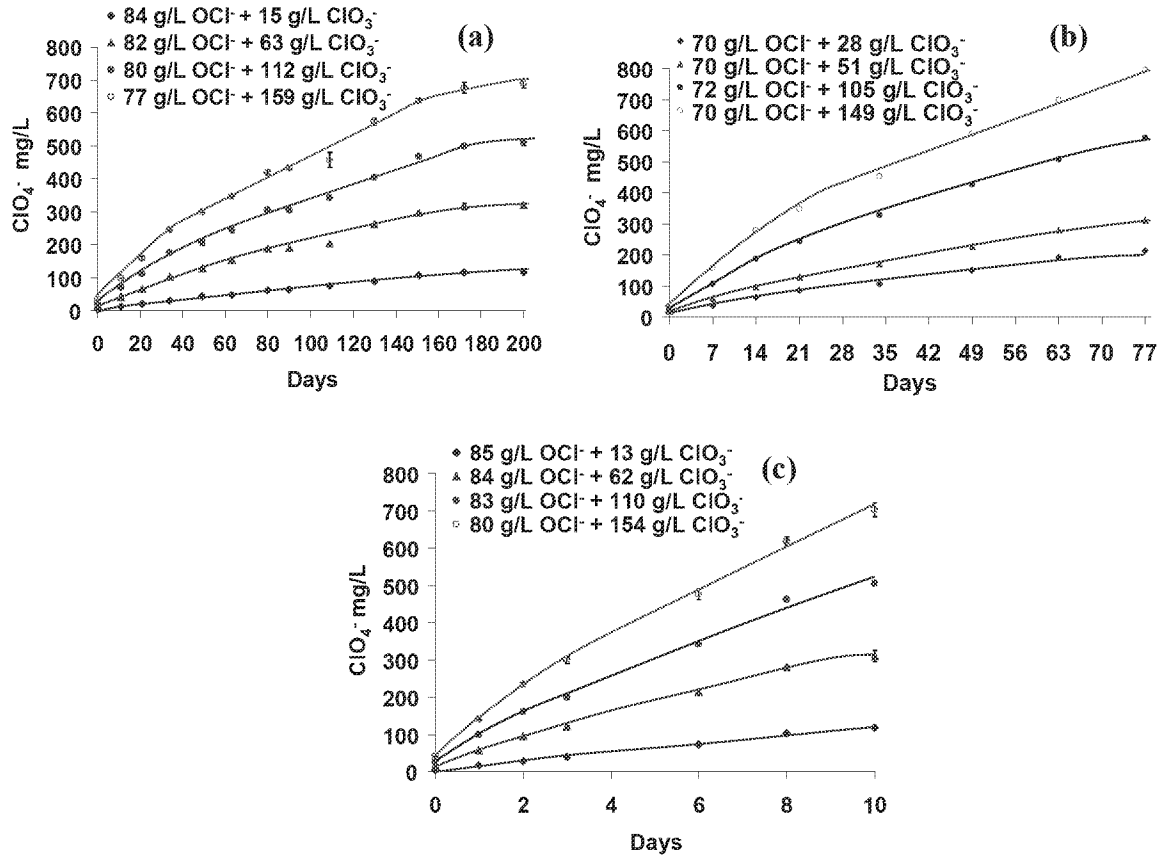

Figure 3.1 Formation of perchlorate as measured by LC-MS/MS for constant hypochlorite / variable chlorate, at (a) 30 °C, (b) 40 °C , and (c) 50 °C

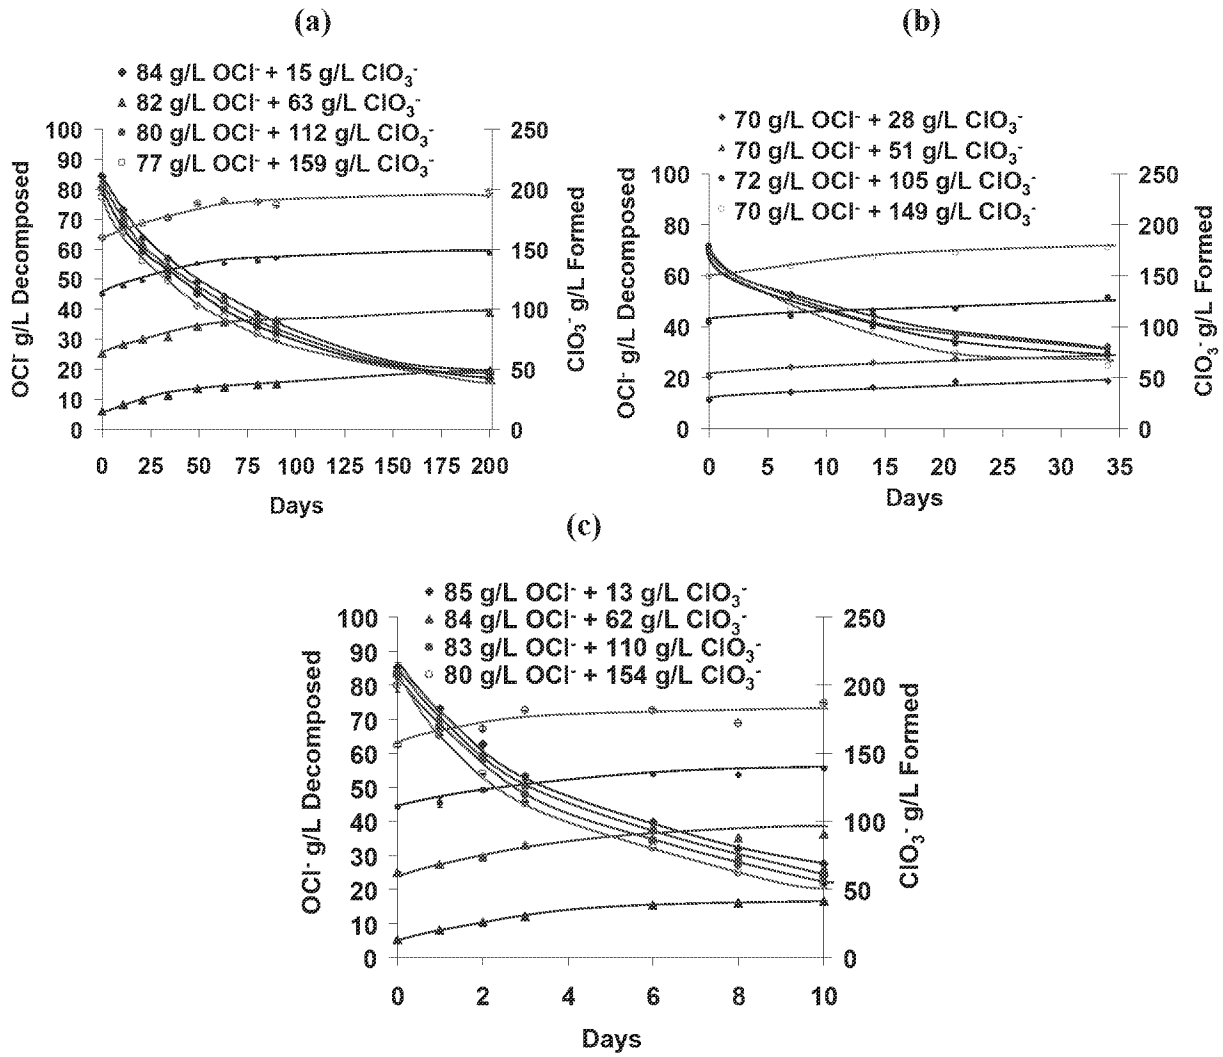

Figure 3.2 Decomposition of hypochlorite and formation of chlorate as measured by titration for constant hypochlorite/variable chlorate, at (a) 30 °C, (b) 40 °C (c) 50 °C

Constant Chlorate/Variable Hypochlorite at 30, 40, and 50 °C

Similar to the effects of variable chlorate ion concentration, the results of this data set provide evidence that changes in hypochlorite ion concentration also affects the rate of formation of perchlorate. Here, hypochlorite ion concentration was varied by dilution while appropriate amounts of sodium chlorate were added to keep chlorate ion concentration the same for all samples. Typically three or more hypochlorite ion concentrations were studied. Figure 3.3 shows plots of average concentrations of perchlorate ion (based on duplicate samples) at different temperature and associated errors of measurements at each temperature. The results presented in Figures 3.4 demonstrate the effects of different initial chlorate ion concentrations on the decomposition of hypochlorite ion and formation of chlorate ion at 30 °C (a), at 40 °C (b), and at 50 °C (c). Similar to chlorate ion involvement, hypochlorite ion is also involved in formation of perchlorate; samples containing lower hypochlorite ion concentrations show less perchlorate formed.

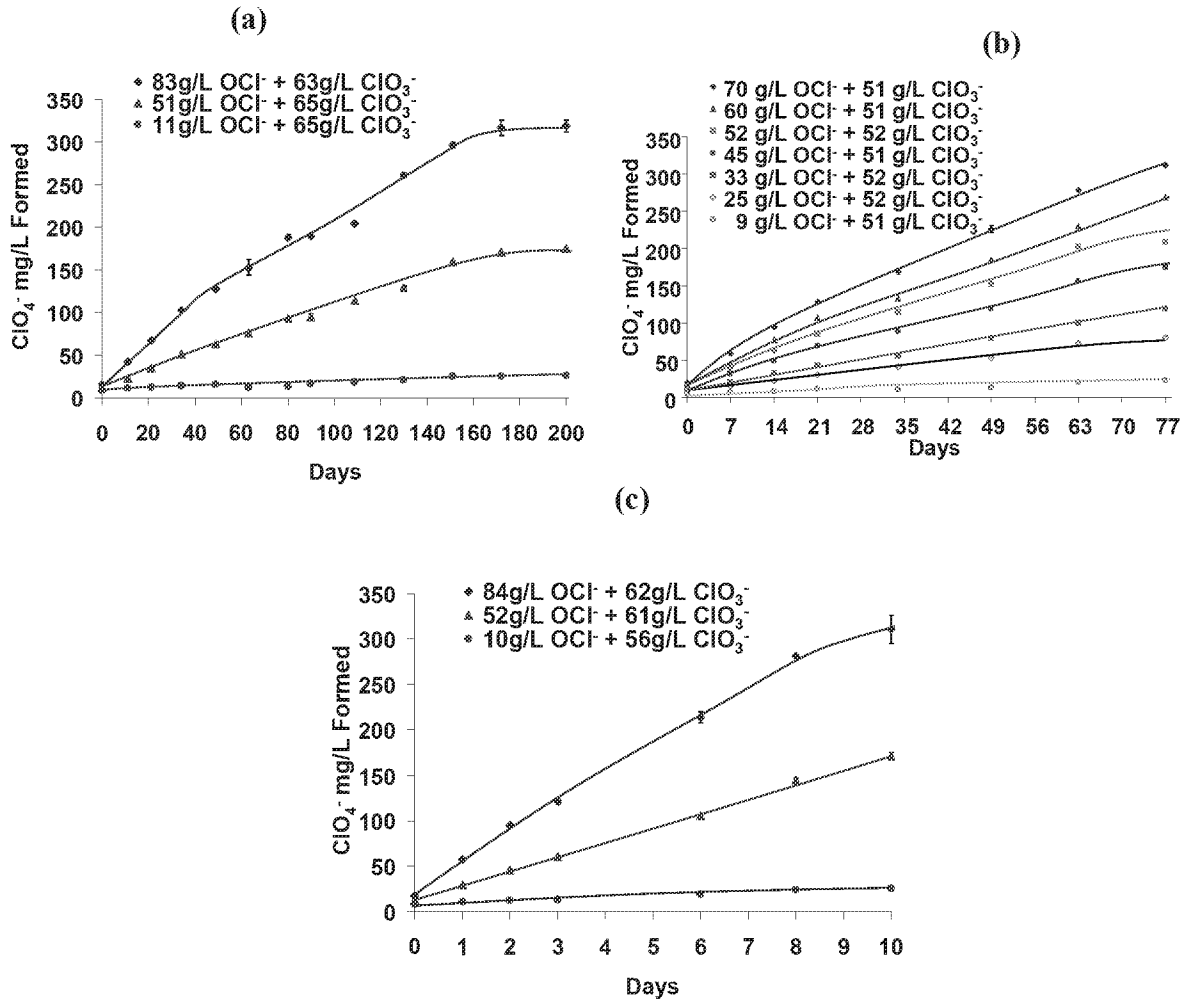

Figure 3.3 Formation of perchlorate as measured by LC-MS/MS for variable hypochlorite, constant chlorate, at (a) 30 °C, (b) 40 °C, and (c) 50 °C

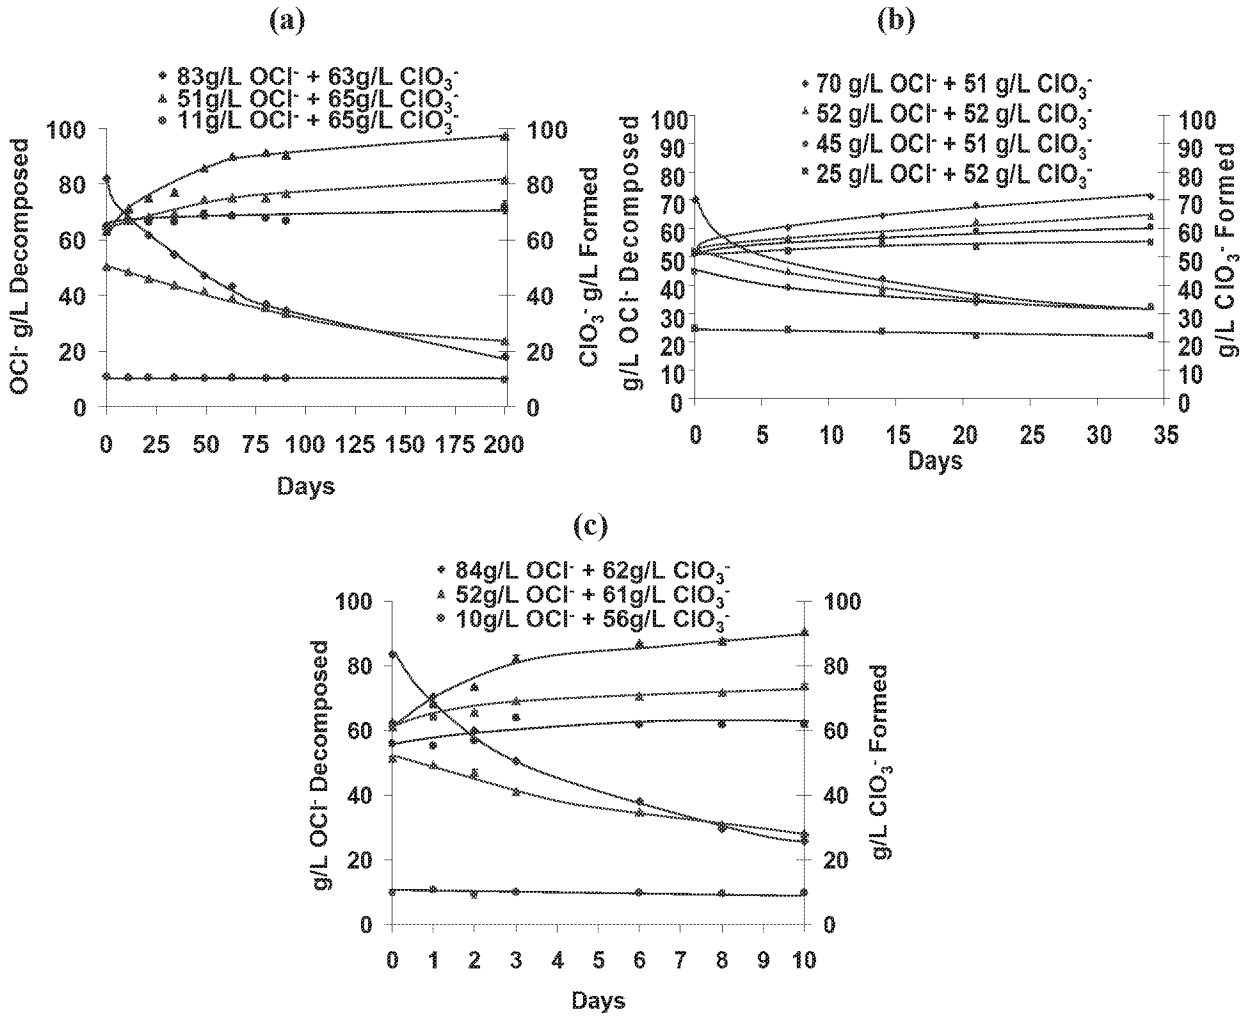

Figure 3.4 Decomposition of hypochlorite and formation of chlorate as measured by titration for variable hypochlorite / constant chlorate, at (a) 30 °C, (b) 40 °C, and (c) 50 °C

Constant Molar Product of [Hypochlorite] x [Chlorate]

Because the rate of perchlorate formation appeared to be first order in chlorate and hypochlorite ions, it was expected that when the molar product was kept constant, the same rate of perchlorate formation would be observed between samples. Both hypochlorite and chlorate ion concentrations were varied in such a way that the molar product was kept constant (1.9% RSD for 30 °C set and 13.4% RSD for 50 °C) and the samples were incubated at 30 °C and 50 °C. Figure 3.5 shows plots of average concentration of perchlorate ion (based on duplicate samples) and associated errors of measurements at each temperature. Figure 3.6 shows the decomposition of hypochlorite ion and formation of chlorate ion at each temperature.

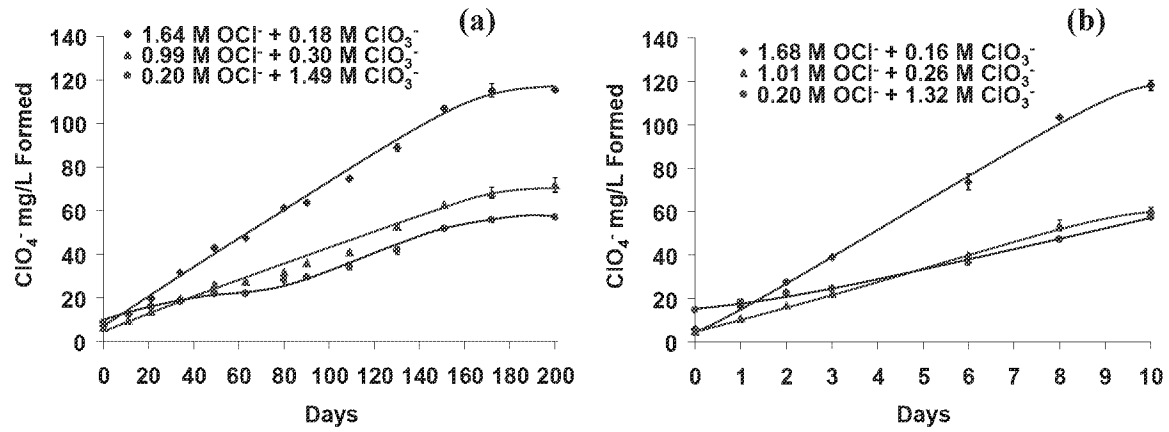

Figure 3.5: Formation of perchlorate as measured by LC-MS/MS for constant [OCl^-] x [ClO_3^-], (a) 30 °C, (b) 50 °C

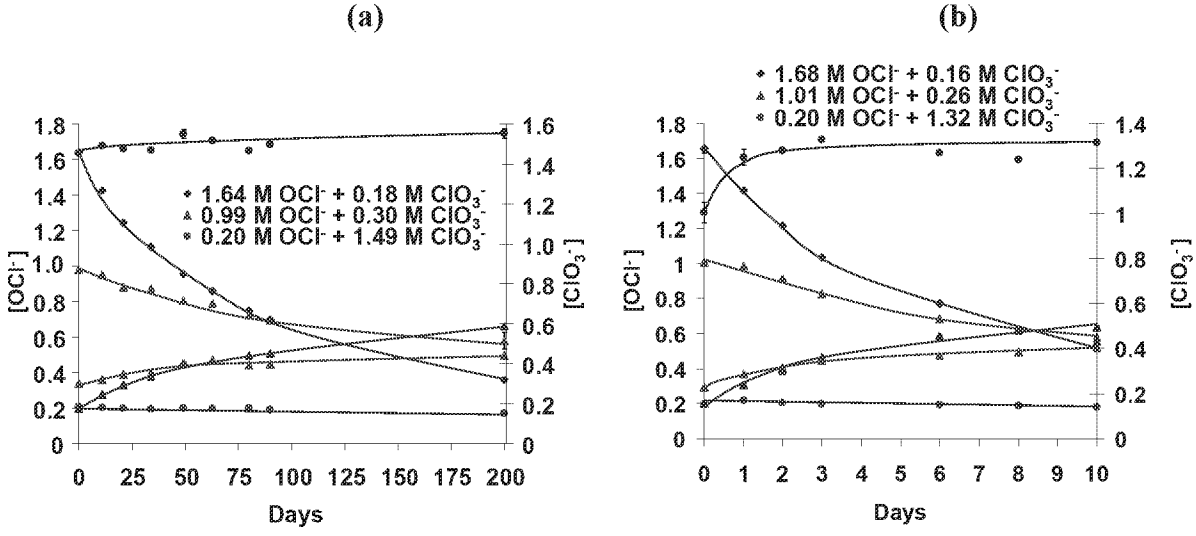

Figure 3.6 Decomposition of hypochlorite and formation of chlorate as measured by titration for constant [OCl^-] x [ClO_3^-], (a) 30 °C, (b) 50 °C

It is immediately evident from Figure 3.5 (a, b) that the assumption of first order in both hypochlorite ion and chlorate ion may have been incorrect OR that other factors (e.g., ionic strength, pH) may have been impacting the results. More perchlorate ion was formed in the sodium hypochlorite solution having higher initial hypochlorite ion concentration than those with lower concentration. The test solutions with higher initial hypochlorite ion concentration appeared to produce similar perchlorate ion concentration initially but began to deviate with time (Figure 3.6). To verify that the samples were indeed constant in molar product of [OCl^-] and [ClO_3^-], the measured concentrations were used to calculate the changes in molar product over time. Changes in the molar product of hypochlorite and chlorate ions over the experimental incubation period are listed in Tables 3.1 and 3.2, while the data are presented graphically in Figure 3.7.

Table 3.1

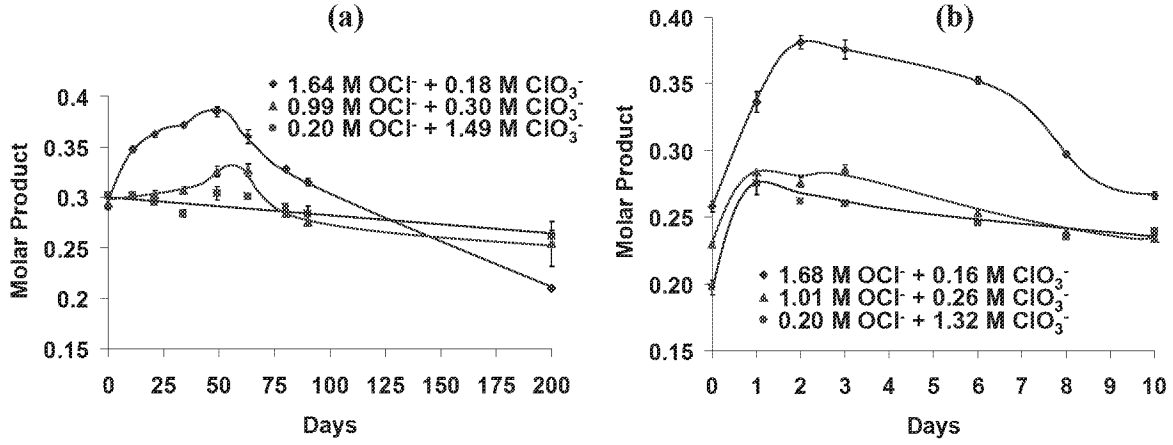

Figure 3.7 Changes in molar product of $[OCl^-]$ x $[ClO_3^-]$ (a) 30 °C, (b) 50 °C

The discrepancy in the perchlorate ion formation results between the three sets of constant molar-product experiments and the fact that initial molar products were within 10% suggests several possibilities: (1) The order with respect to hypochlorite may be higher than one. This can be inferred in part from the observation that in the two lowest [OCl^-] concentration samples, the changes in molar product were in better agreement than the high [OCl^-] concentration sample. Such a result suggests a dependence on hypochlorite ion concentration which is different from the dependence on chlorate ion. Thus, the order of perchlorate formation may still be one with respect to chlorate. (2) The rate of perchlorate formation may be dependent on another variable not considered during the initial design of the constant-molar-product experiments. One would expect that as a concentrated sodium hypochlorite solution is diluted (even with subsequent addition of sodium chlorate), the ionic strength and/or pH would also change. Indeed this was the case: Table 3.3 shows the ionic strength variance with dilution of the stock concentrated sodium hypochlorite solution. While pH did not vary by more than 0.8 pH units, the ionic strength varied by nearly 3 fold during dilution. Thus, ionic strength was suspected as an important factor in determination of the rate law for perchlorate formation.

Table 3.3
Ionic strength and constant-molar-product experiments at 30 and 50 °C

30 °C Experiment:	[OCl^-]	[ClO_3^-]	Ionic strength (M)		pH
[OCl^-]x[ClO_3^-]: 1.64M x 0.178M	1.637	0.178	6.50		12.88
[OCl^-]x[ClO_3^-]: 0.986M x 0.298M	0.977	0.302	4.23		12.69

50 °C Experiment:					
[OCl^-]x[ClO_3^-]: 1.68M x 0.158M	1.658	0.156	6.31		12.89
[OCl^-]x[ClO_3^-]: 1.01M x 0.264M	1.008	0.228	4.20		12.69
[OCl^-]x[ClO_3^-]: 0.202M x1.32M	0.196	1.006	2.66		12.11
				Mean	12.56± 0.41

Chlorite Ion Effects

Chlorite ion concentration typically reaches steady state in hypochlorite solutions and is an intermediate in the formation of chlorate (Lister 1956; Adam, et al. 1992; Adam and Gordon 1999). Thus, when sodium chlorite is added to a sodium hypochlorite solution, chlorite ions can be expected to react with hypochlorite to produce chlorate ions based on the reactions described in Equations 3.5 and 3.6:

$$OCl^- + OCl^- \longrightarrow ClO_2^- + Cl^- \qquad k_{ClO2-}(\text{slow}) \qquad \textbf{(3.5)}$$

$$OCl^- + ClO_2^- \longrightarrow ClO_3^- + Cl^- \qquad k_{ClO3-}(\text{fast}) \qquad \textbf{(3.6)}$$

To determine whether chlorite ion could represent an additional perchlorate ion formation pathway, chlorite ion was spiked at 15 g/L with and without an additional spike of chlorate ion at 100 g/L. Formation of perchlorate for the 30 °C and 50 °C incubation studies is shown in Figure 3.8. Figure 3.9 shows the change in perchlorate ion concentration overlaid with changes in the molar product at each temperature. Decomposition of hypochlorite ion overlaid with the formation of chlorate ion is shown in Figures 3.10. The data indicate the addition of chlorite ion does not appear to offer a substantial change in perchlorate formation beyond what would be observed from the addition of chlorate ion represented in Equations 3.5 and 3.6. This is especially evident when the molar product of chlorate and hypochlorite are considered (Figure 3.9 (a, b)), showing nearly identical changes over time.

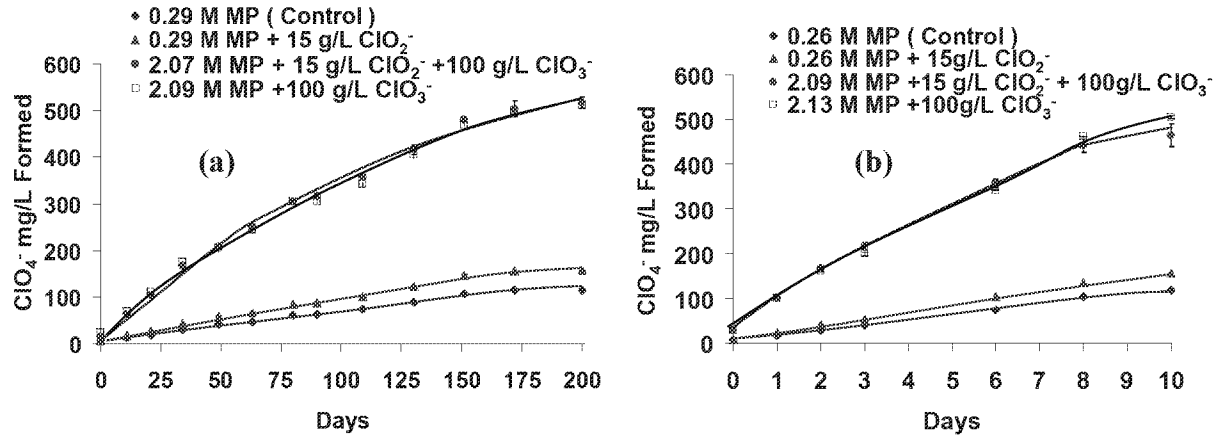

Figure 3.8 Formation of perchlorate measured by LC-MS/MS, effects of chlorite, (a) 30 °C, (b) 50 °C (MP = [OCl⁻]X[ClO_3^-])

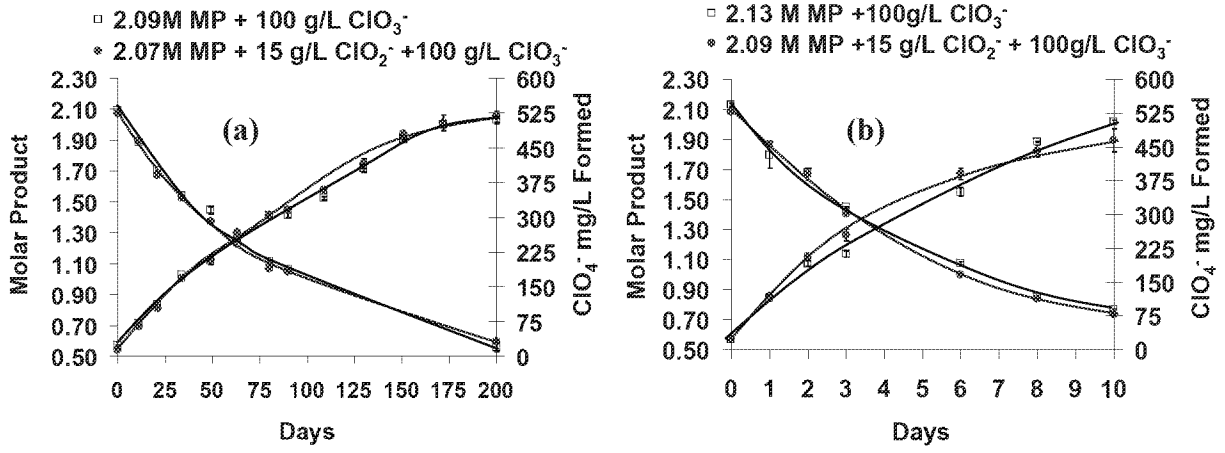

Figure 3.9 Comparison of changes in molar product (MP = [OCl⁻]X[ClO_3^-]) over time and the concomitant formation of perchlorate, effects of chlorite, (a) 30 °C, (b) 50 °C

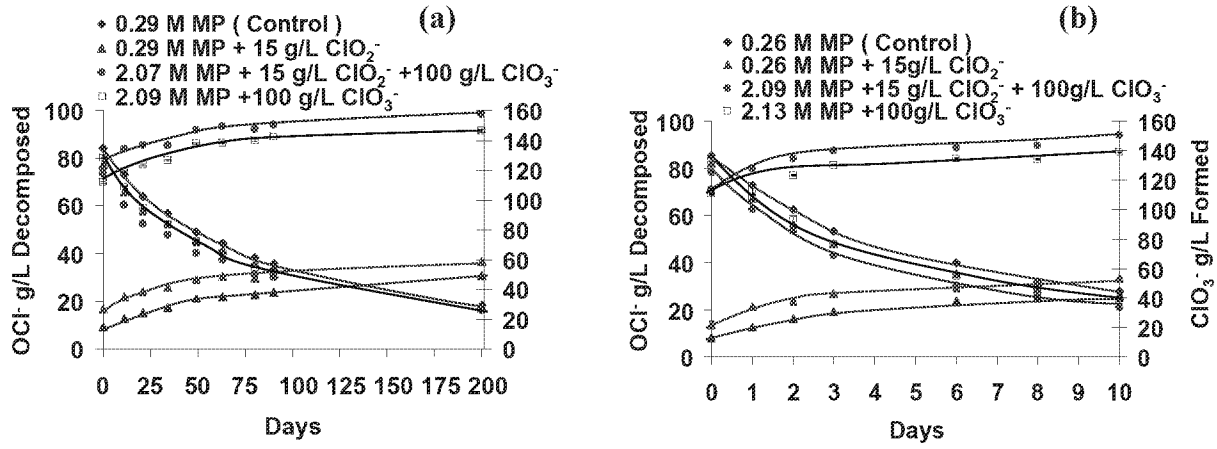

Figure 3.10 Decomposition of hypochlorite and formation of chlorate measured by titration effects of chlorite, (a) 30 °C, (b) 50 °C (MP = [OCl^-]X[ClO_3^-])

In summary, ClO_2^- reacts with OCl^- to form ClO_3^-, affecting the formation of ClO_4^- in two ways: The first effect is due to the conversion of chlorite ion to chlorate ion, enhancing the formation of perchlorate ion. The second effect, however, occurs at the same time whereby hypochlorite ion concentration is concomitantly reduced, thus decreasing the rate of formation of perchlorate ion. The combined outcome is that more perchlorate ion formation can be observed in chlorite ion-spiked hypochlorite solutions than control solutions. However, in samples spiked with both chlorite ion and high levels of chlorate ion, this effect is not as significant. The lower accumulation of perchlorate ion correlates to observed similarities in the molar product of the chlorate ion-spiked sample and chlorite/chlorate ion-spiked sample. The addition of chlorite ion does not enhance the rate of perchlorate ion formation mechanistically, however. Thus, it was determined that chlorite ion concentration was neither a significant factor in the kinetics of perchlorate ion formation nor in determination of the chemical rate law.

Metal Ion Effects

The potential catalytic effect of transition metal ions was initially investigated at 75 °C and evaluated the combined effects of Co^{2+}, Cu^{2+}, Fe^{3+}, Mn^{2+}, and Ni^{2+} at 20 mg/L final concentration. At this combination of temperature and concentration, the decomposition reaction of hypochlorite was too rapid to measure, and thus the effects (if any) of transition metals on the actual formation of perchlorate could not be observed. In a follow-up incubation study, 2 mg/L and 0.2 mg/L concentrations of metals were used in spiked hypochlorite solutions. Figure 3.11 (a) shows the concurrent loss of hypochlorite ion and formation of chlorate ion in the presence of transition metal ions. These results indicate that the metal ions catalyze a rapid decomposition of hypochlorite (as previously described by Adam 1994; Gordon, et al. 1997; Adam and Gordon 1999), overwhelming any possible effects that might have been observed during the catalysis of perchlorate formation. Therefore, rather than catalyzing perchlorate formation, the presence of the metal ions actually assist in the minimization of perchlorate ion formation at the expense of a loss of hypochlorite ion concentration in the hypochlorite solution as shown in Figure 3.11 (b).

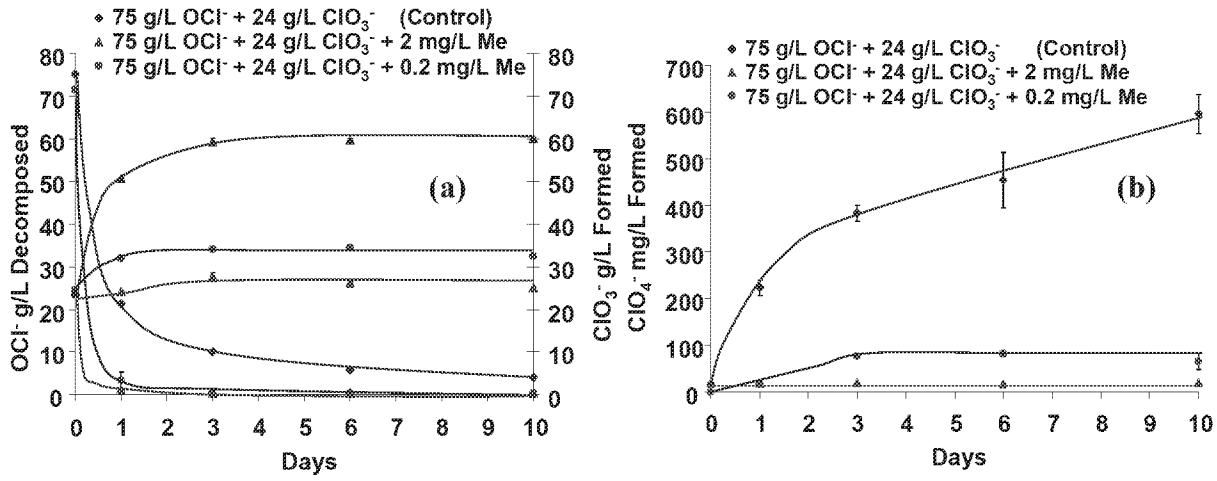

Figure 3.11 Effects of transition metals ions (Me = Co^{2+}, Cu^{2+}, Fe^{3+}, Mn^{2+}, Ni^{2+}): (a) decomposition of hypochlorite (downward sloping curves) & formation of chlorate (upper curves); (b) formation of perchlorate

The combined effects of chlorite ion, transition metals ions (Co^{2+}, Cu^{2+}, Fe^{3+}, Mn^{2+}, and Ni^{2+}), and bromide ion on formation of perchlorate and chlorate were also investigated by incubating liquid hypochlorite samples at 50 °C with the following amounts of chlorite ion, chlorate ion, and/or transition metal ion spikes, in duplicate:

Spike 1: ClO_2^- at 15 g/L + Transition Metals Spike at 0.2 mg/L

Spike 2: ClO_2^- at 15 g/L + ClO_3^- Spike at 100g/L + Transition Metals Spike at 0.2 mg/L

Spike 3: ClO_2^- spike at 15 g/L + Br^- at 15 g/L

Figure 3.12 shows the average concentration of perchlorate vs. time for each of the spike experiments listed above. As predicted from previous experiments, the addition of chlorite with the transition metal ions does not appear to have a synergistic effect on the formation of perchlorate, though the high chlorate/chlorite ion spike was able to increase the rate of perchlorate ion production beyond that of the control (likely due to the dependence upon chlorate ion concentration).

As a follow-up experiment, noble metals ions were spiked into sodium hypochlorite solutions as a group (Ag^+, Au^+, Ir^+, Pd^+, Pt^+) at 0.2 mg/L while iridium ion was also spiked alone into a second set of solutions at 0.2 mg/L:

Spike 4: Noble Me Ions (Ag^+, Au^+, Ir^+, Pd^+, Pt^+) at 0.2 mg/L

Spike 5: Iridium Ion (Ir^+) at 0.2 mg/L

Table 3.4 provides perchlorate ion concentration results tabulated per day, showing no effect from the presence of noble metal ions on perchlorate ion formation. These data are represented graphically in Figure 3.13, lending further evidence to the lack of involvement by the tested noble metal ions on hypochlorite decomposition and perchlorate formation. Perchlorate

ion concentration in spiked samples and control samples appears to be of the same statistical data set (i.e, as if replicate samples of the same hypochlorite ion solution), leading to the conclusion that the noble metal ions at 0.2 mg/L concentration have very little or no effect.

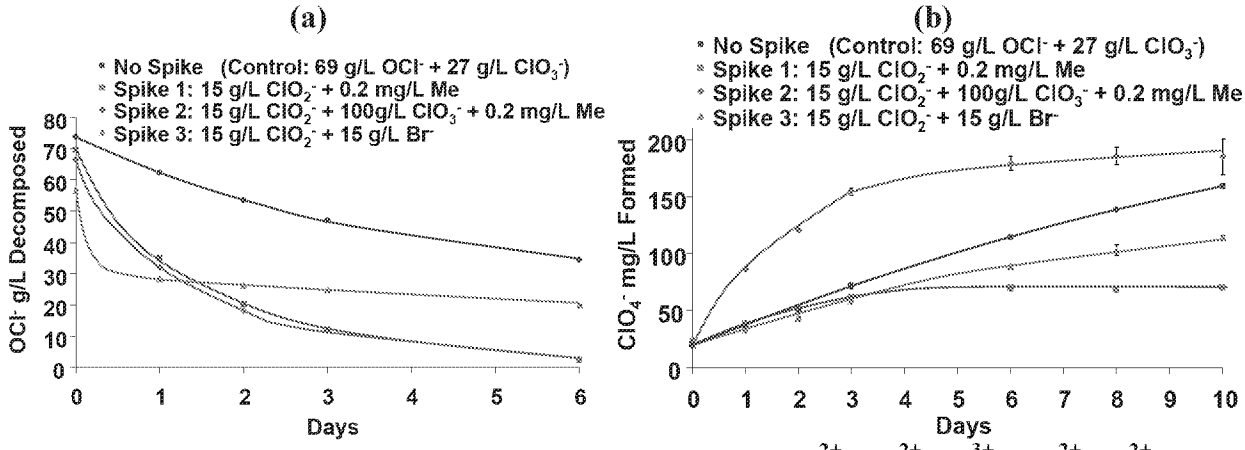

Figure 3.12 Effects of transition metals ions spikes (Me = Co^{2+}, Cu^{2+}, Fe^{3+}, Mn^{2+}, Ni^{2+}), 1.7 M hypochlorite, at 50 °C, (a) decomposition of hypochlorite; (b) formation of perchlorate

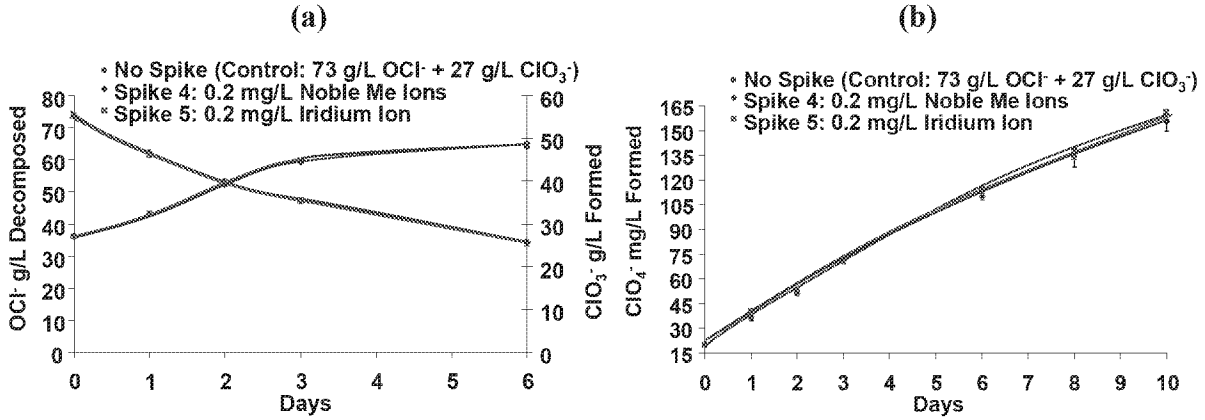

Figure 3.13 Effects of noble metals ions (Noble Me Ions =Ag^+, Au^+, Ir^+, Pd^+, Pt^+) spikes, 1.7 M hypochlorite, 50 °C (a) decomposition of hypochlorite; (b) formation of perchlorate

In summary, transition metals are unable to enhance perchlorate ion formation because they catalyze a rapid decomposition of hypochlorite ion which is needed to form perchlorate. Thus, perchlorate can theoretically be minimized under conditions which also result in a loss of hypochlorite (though this would be disadvantageous for the utility). Chlorite and transition metals do not appear to have a synergistic effect on formation of perchlorate. Hypochlorite solutions spiked with both contaminants produced perchlorate levels significantly lower than control solution. Noble metal ions spiked at 0.2 mg/L also showed little or no effect on the amount of perchlorate formed.

Bromide and Bromate Ion Effects

The effects of bromide and bromate on formation of perchlorate, bromate, and chlorate were investigated by incubating 13% bulk hypochlorite samples at 50 °C spiked with the following amounts of bromide and/or bromate, in duplicate:

Br^- Spike at 15 g/L, BrO_3^- Spike at 15 g/L, or Br^- + BrO_3^- Spike at 15 g/L

Br^- Spike at 30 g/L, BrO_3^- Spike at 30 g/L, or Br^- + BrO_3^- Spike at 30 g/L

Bromate ion concentration over time was monitored by LC-MS/MS and is shown in Figure 3.14-(a) while the change in hypochlorite ion concentration is shown in Figure 3.14 (b). Change in perchlorate ion concentration is shown in Figure 3.15.

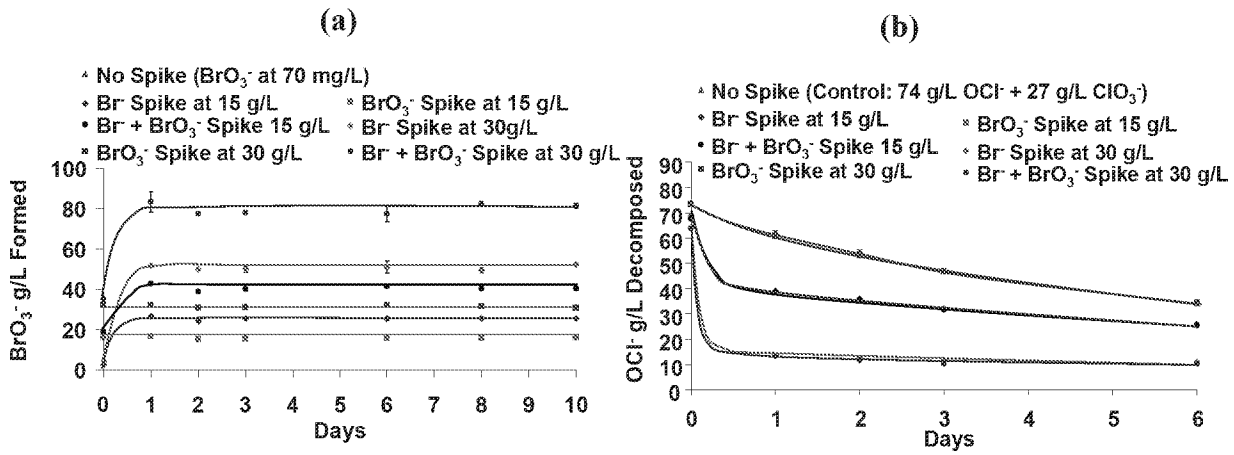

Figure 3.14: Effects of bromide and bromate, 1.7 M hypochlorite, 50 °C, (a) formation of bromate, (b) decomposition of hypochlorite

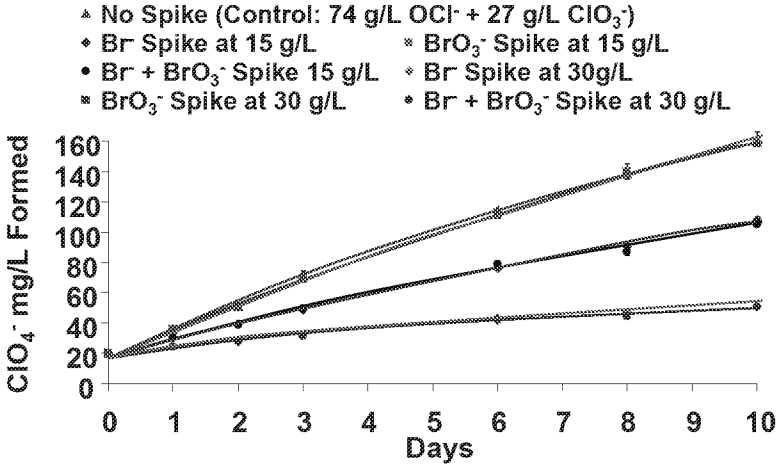

Figure 3.15 Formation of perchlorate as measured by LC-MS/MS, bromide and bromate spikes, 1.7 M hypochlorite, 50 °C

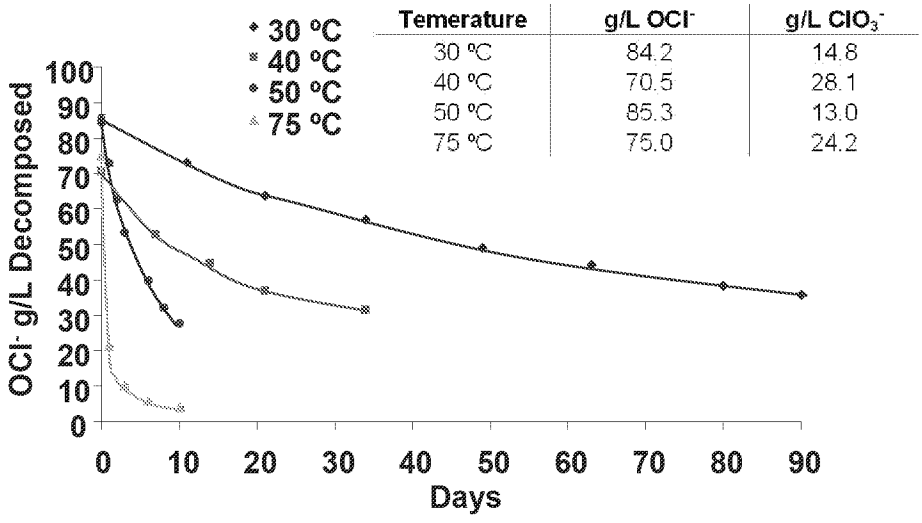
It is clear from the data that bromide ion rapidly reacts (within 1 day) with hypochlorite ion to produce bromate, hypothetically via the formation of hypobromite in a reaction mechanism similar to that of chlorate ion. The formation of perchlorate ion over time (Figure 3.15) is largely unaffected by the presence of bromate ion in solution. The presence of bromide ion did reduce the amount of perchlorate ion formed, but is likely not directly related to bromide. Instead, the reduction in the rate of perchlorate ion formation is likely due to the loss of hypochlorite ion in a reaction of bromide to produce bromate, thereby reducing the amount of hypochlorite available to produce perchlorate. The effect of the presence of bromide ion is similar to that of the transition metals ions in the sense that both types of contaminant react with available hypochlorite to produce species different than the perchlorate (e.g., transition metal

catalyze decomposition of hypochlorite to produce oxygen gas, bromide is converted to bromate), thereby reducing the available hypochlorite ion for perchlorate ion formation.

Temperature Effects

The decomposition of sodium hypochlorite solutions is strongly dependent on temperature. Both the rate of hypochlorite decomposition and the rate of chlorate formation increase with increase in temperature as observed in each of the studies listed in this Chapter (see also Figures 3.16 and 3.17) and elsewhere. The effects of temperature and ionic strength have been thoroughly investigated and a comprehensive predictive model has been developed (Adam and Gordon 1999). In this study, the effect of temperature on the formation of perchlorate ion over time was also investigated. Multiple hypochlorite solutions were incubated at temperatures ranging from 30 °C to 75 °C in order to quantify the relationship between perchlorate ion formation and temperature. Results of changes in perchlorate ion concentration from several of the studies are summarized in Figure 3.18 (hypochlorite and chlorate ion concentrations form the same experiments are summarized in Figures 3.16 and 3.17). Although the hypochlorite solutions varied in chlorate ion concentration, qualitatively one can still see that the rate of perchlorate ion formation is also strongly dependent on temperature. Thus, temperature effects were incorporated into the detailed chemical rate law discussed in Chapter 4.



Temerature	g/L OCl^-	g/L ClO_3^-
30 °C	84.2	14.8
40 °C	70.5	28.1
50 °C	85.3	13.0
75 °C	75.0	24.2

Ionic Strength Effects

Given that higher ionic strength increases the rate of decomposition of hypochlorite ion and increases the rate of chlorate ion formation (Adam 1994; Gordon, et al. 1997; Adam and Gordon 1999), it was hypothesized that a higher ionic strength would likewise increase the rate of perchlorate ion formation. To investigate effects of ionic strength on formation of perchlorate, solutions of sodium hypochlorite were incubated at 40 °C and 60 °C with different ionic strengths achieved by dilution and/or spiking with sodium chloride. Three groups of samples were incubated at 40 °C, each having varying chloride ion concentration (used to vary ionic strength), constant hypochlorite ion concentration, and a different chlorate ion concentration for each of the three groups. Another set of solutions was incubated at 60 °C and had the same initial hypochlorite and chlorate ion concentrations but varied by sodium chloride concentration.

Figure 3.19 shows the *Bleach 2001* (Adam, Gordon, and Pierce 2001) predicted decomposition of hypochlorite ion and subsequent formation of chlorate ion when additional chloride ions are added to the solution. As expected, increasing the ionic strength by chloride ion addition increases the rates of formation of chlorate ion and disappearance of hypochlorite ion. In Figures 3.20 and 3.21, similar effects are observed on the formation of perchlorate ion with respect to ionic strength at 40 °C and 60 °C. In figure 3.21, the high ionic strength and high temperature resulted in a plateau of perchlorate ion concentration due to a rapid depletion of hypochlorite ion concentration. However, unlike in the metal ion experiments whereby a rapid loss of hypochlorite resulted in little additional perchlorate ion formation, here ionic strength increased the rate *and* the total amount of perchlorate ion produced in each solution. Similar impacts on hypochlorite ion, chlorate ion, and perchlorate ion concentrations were observed in each of the ionic strength – temperature paired experiments (data not shown).

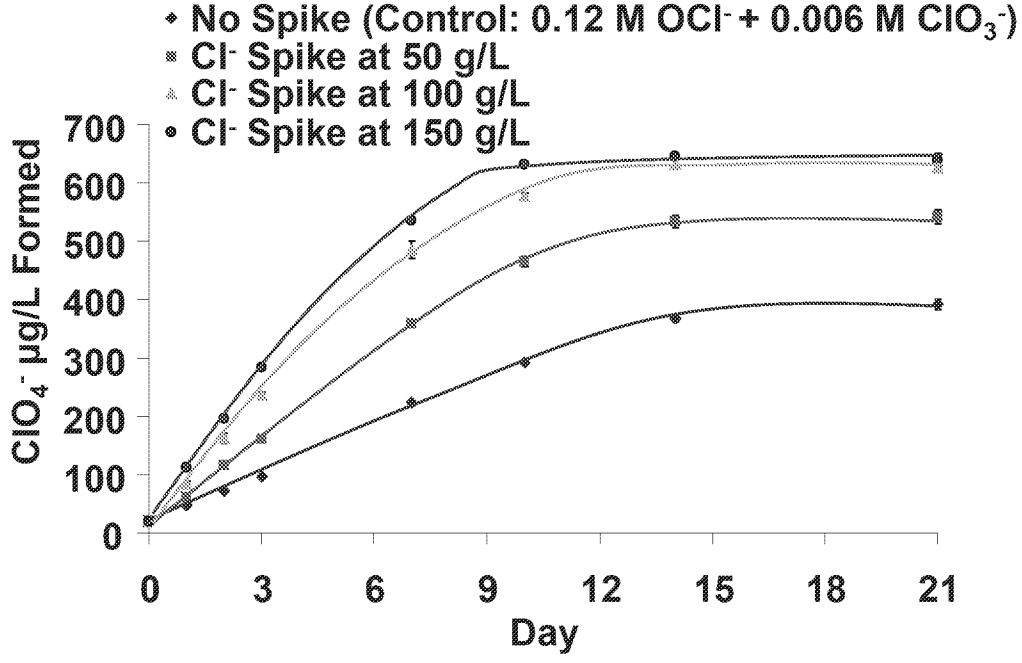

Figure 3.21 Formation of perchlorate in Hypochlorite solutions spiked with variable amounts of chloride ion at 60 ºC

Effects of pH

Sodium hypochlorite solutions are most stable in the pH 12-13 range (Adam 1994; Adam and Gordon 1999). Above pH 13, the hydroxide ion concentration exerts an ionic strength effect on the decomposition of hypochlorite ion. Below pH 11 however, an acid-catalyzed decomposition of hypochlorite ion begins to occur. At pH values lower than 10.5 this rate of decomposition continues to increase. In the pH 11 – 14 range, the decomposition of hypochlorite ion is second order in hypochlorite; in the pH 5 – 9 range, the decomposition is third order in hypochlorite. As such, there is some discontinuity that can be observed between pH of 9 and 11 in the decomposition of hypochlorite (Adam and Gordon 1999). Current guidelines recommend that sodium hypochlorite solutions should be stored in the pH 12-13 region where both the decomposition of hypochlorite ion and the formation of chlorate ion are minimized. Perchlorate ion formation, as has already been shown during the course of this report, is dependent on concentrations of hypochlorite ion, chlorate ion, and ionic strength. Thus, it is reasonable to assume that because pH affects hypochlorite ion decomposition and chlorate ion formation, pH may also affect perchlorate ion formation.

To study the pH effects on perchlorate ion formation, sodium hypochlorite solutions were prepared at three pH values (13, 11, and 9) and incubated at 40 °C. Figure 3.22 (a) shows the changes in perchlorate ion concentration over time and Figure 3.22 (b) shows the decomposition of hypochlorite ion and formation of chlorate ion of the same sodium hypochlorite solution incubated at 40 °C.

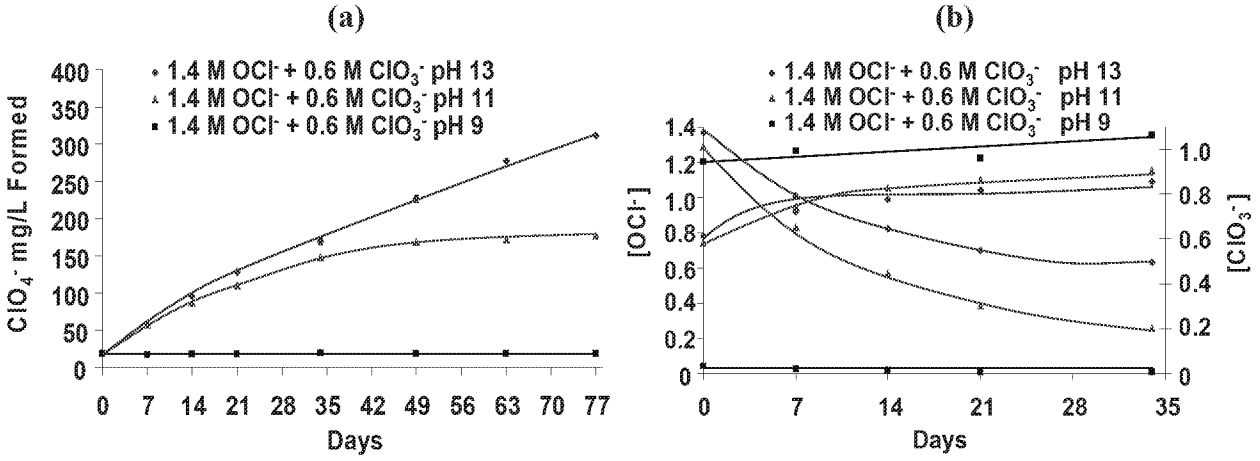

Figure 3.22 Plots of (a) perchlorate concentration vs. time; (b) hypochlorite and chlorate concentration vs. time in sodium hypochlorite solutions with initial [OCl^-] = 1.4 M and initial [ClO_3^-] =0.6 M at pH 13, 11, and 9 incubated at 40 °C

As observed in figure 3.22 (a), the increase in perchlorate ion concentration in solution adjusted to pH 9 is not appreciable above the starting concentration. However, the data presented in Figure 3.22 (b) indicate that at pH 9 the decomposition of hypochlorite ion was so rapid that by the time of analysis only trace amounts of hypochlorite ion could be detected. Thus, the effect of pH 9 during this experiment on the rate of perchlorate ion formation was inconclusive, but indicates that decreasing the pH in concentrated sodium hypochlorite solutions may affect the rate of perchlorate formation. The same conclusion was drawn from experimental data presented in Figure 3.23 (a, b). From a practical stand point, 13% NaOCl solution at pH 12.9 has a half-life of 197 days at 25 °C (*Bleach 2001* prediction), whereas the actual Hypochlorite solution adjusted to pH 9 decomposed in a matter of hours. Each of the pH-perchlorate figures presented here indicate that at pH values lower than 13 (which served as the control), there is less perchlorate ion formed. This result can be explained by the fact that at lower pH values the decomposition of hypochlorite ion and formation of chlorate ion are enhanced, leading to faster hypochlorite ion consumption and therefore less perchlorate ion formation.

To investigate more thoroughly the impact of pH in the 9 – 11 regions, a follow-up incubation study at 60 °C was conducted on OSG Hypochlorite produced at SNWA (more dilute than bulk and at a lower pH) and adjusted with NaOH to vary the pH. The stock solution (control) of sodium hypochlorite had a pH of 9.35. Aliquots of this solution were adjusted to pH =10.65, 11.90 and 13.3 by addition of sodium hydroxide and then incubated at 60 °C. As expected, the control solution at pH 9.35 had the fastest rate of hypochlorite ion decomposition, and the fastest rate of chlorate ion formation as shown in Figures 3.24 (a, b) and 3.25.

Interestingly, the rate of perchlorate ion formation was also enhanced in the sodium hypochlorite solution having an initial pH of 9.35 (Figure 3.25) though the overall perchlorate concentration at the end of the experiment was less than or the same as the other solutions tested at different pH. The hypochlorite solutions with initial pH values of 10.65 and 11.90 produced very similar amounts perchlorate ion, while solution with pH 13.30 produced more perchlorate by 21 days of incubation, and had the second fastest rate of perchlorate formation. This can be explained by the fact that the ionic strength of pH=13.30 solution was significantly higher than the rest. Table 3.5 shows ionic strength and total dissolved solids of each solution derived from specific conductance measurements.

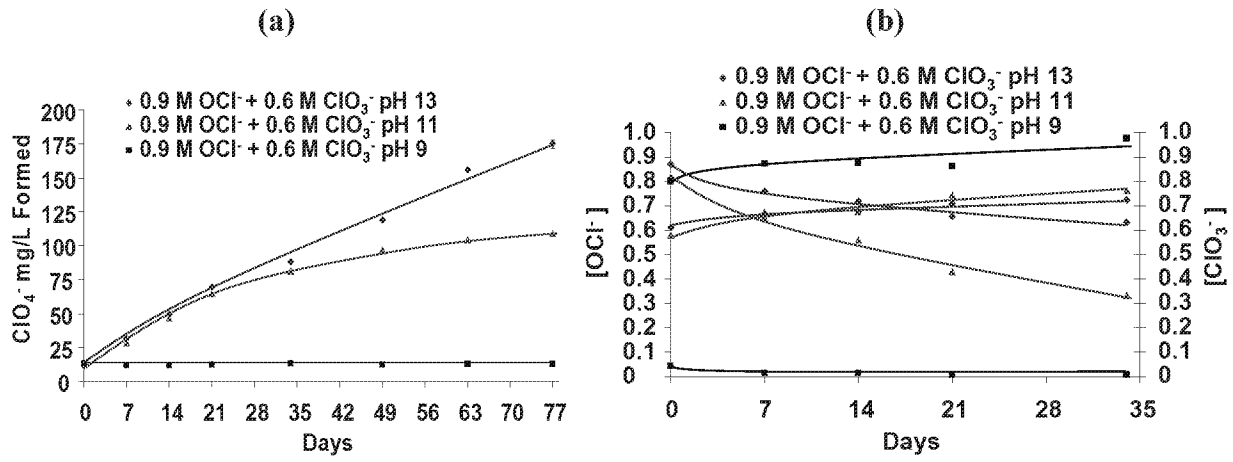

Figure 3.23 Plot of (a) perchlorate concentration vs. time in sodium; (b) hypochlorite and chlorate concentration in hypochlorite solutions with initial [OCl^-] = 0.9 M and initial [ClO_3^-] = 0.6 M at pH 13, 11, and 9, incubated at 40 °C

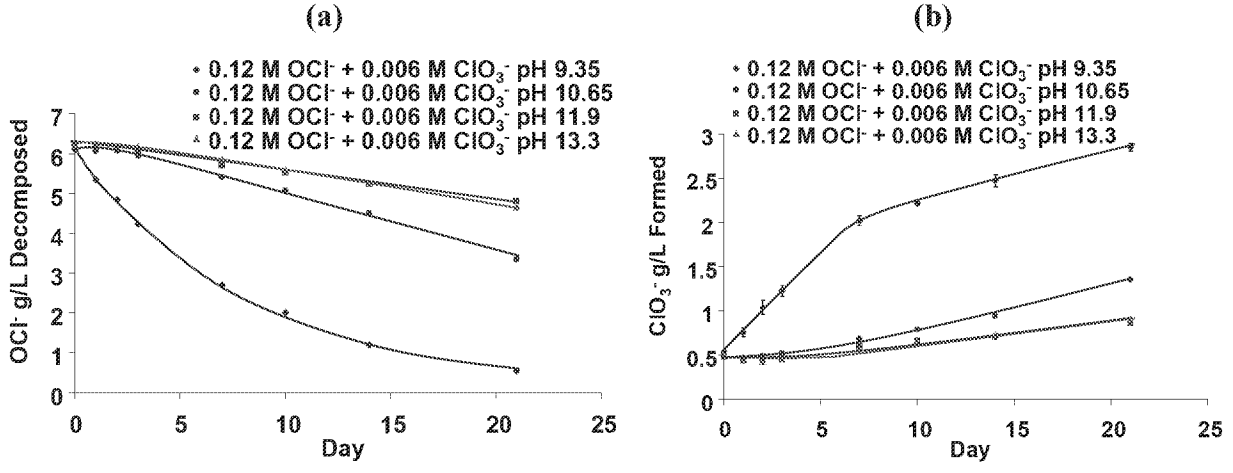

Figure 3.24 Effect of pH on hypochlorite decomposition (a) and chlorate formation (b) in OSG hypochlorite solutions at 60 °C

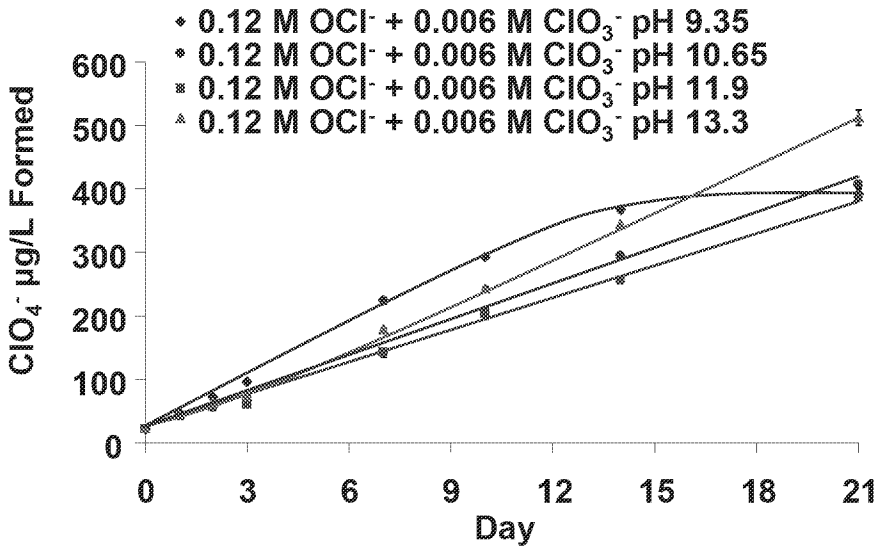

Figure 3.25 Effect of pH on perchlorate formation in OSG hypochlorite solutions at 60 °C

Enhancement of the initial rate of perchlorate ion formation at pH 9.35 suggests that there may be a pH dependence. However, over time the amount of perchlorate produced at this pH compared to higher pH is less due to the more rapid decrease in hypochlorite ion concentration at the lower pH. From a practical standpoint, the pH effect is not significant since most of bulk sodium hypochlorite solutions have a pH above 11 and OSG Hypochlorite is rarely stored for more than 24 to 48 hours. Furthermore, the impact of ionic strength observed from adjusting the pH with sodium hydroxide points towards the issue of ionic strength acting as a "master variable" (in addition to hypochlorite ion concentration and chlorate ion concentration) that out-weighs any pH effects that might be observed.

Table 3.5
Ionic strength and Total Dissolved Solids (TDS) of sodium hypochlorite solutions with initial [OCl^-]=0.120 ±0.001M (Measured by titration), [ClO_3^-]=0.006±0.0003 (measured by LC-MS/MS) with pH adjusted using NaOH

SUMMARY

The data presented in this Chapter represent the experimental work designed to determine the factors impacting perchlorate ion formation in sodium hypochlorite solutions. The effect investigated included: concentration of hypochlorite and chlorate ions, concentration of chlorite ion, metal ion effects, bromide and bromate ion effects, temperature, ionic strength, and pH. The effects of each of these factors can be grouped into four major categories: (1) Factors directly (mechanistically) impacting the rate of perchlorate formation; (2) Factors indirectly impacting the rate of perchlorate formation by changing hypochlorite ion or chlorate ion concentrations; (3) Factors having no observable effect on perchlorate formation; and (4) Environmental factors.

1. Factors directly (mechanistically) impacting the rate of perchlorate formation

    a. Hypochlorite ion concentration: higher concentration results in a faster rate of perchlorate formation

    b. Chlorate ion concentration: higher concentration results in a faster rate of perchlorate formation

    c. Ionic strength: higher ionic strength results in a faster rate of perchlorate formation

2. Factors indirectly impacting the rate of perchlorate formation by changing hypochlorite ion or chlorate ion concentrations

    a. Metal ions, rather than catalyzing perchlorate formation, actually assist in the minimization of perchlorate ion formation at the expense of a loss of hypochlorite ion concentration in the Hypochlorite solution.

    b. The presence of bromide ion reduces the rate of perchlorate ion formation by consuming hypochlorite ion for the production of bromate ion. Thus, less hypochlorite ion is available for perchlorate ion formation.

    c. Addition of chlorite ion does not enhance the rate of perchlorate ion formation mechanistically. However, chlorite did impact the concentration of hypochlorite and chlorate ions, thereby causing an incremental increase in perchlorate ion formation.

3. Factors having no observable effect on perchlorate formation

    a. BrO_3^-, Ag(I), Au(I), Ir(I), Pt(I), and Pd(I) had no observable effect either on the perchlorate formation, hypochlorite decomposition, or chlorate formation

4. Environmental factors

    a. The impact of pH clearly changes the rate of decomposition of hypochlorite ion. While it is possible that there is a mechanistic

consideration in the formation of perchlorate ion, from a practical standpoint pH is considered an indirect, environmental factor that can be adjusted as needed.

b. Temperature clearly impacts the rate of perchlorate ion formation in addition to the rate of hypochlorite ion decomposition and chlorate ion formation. However, temperature can be adjusted/controlled to some extent, thus was considered an environmental factor

Based on the observations listed above, the controlling variables in the rate of perchlorate ion formation are concentration, ionic strength, temperature, and pH. From a practical standpoint, pH can be ruled out as a contributing factor because it is expected that only bulk hypochlorite solutions with a pH of 11 to 13 will be stored for any period of time. Thus, one environmental factor and three mechanistic factors remain. Any change in concentration of hypochlorite or chlorate strongly impacted the rate of perchlorate formation. However, the inclusion of constant molar product of hypochlorite and chlorite ions into the experimental matrix led to two possible scenarios: the order with respect to hypochlorite may be higher than one OR the rate of perchlorate formation may be dependent on another variable not considered during the initial design of the constant-molar-product experiments (e.g., ionic strength). Therefore, the determination of the rate law of perchlorate ion formation discussed in the next Chapter incorporates considerations of concentrations of hypochlorite and chlorate ions as well as accounting for environmental factors such as ionic strength and temperature.

CHAPTER 4
FORMULATION OF INITIAL MODEL FOR PREDICTING PERCHLORATE FORMATION IN HYPOCHLORITE SOLUTIONS

APPROACH

Detailed in the summary of Chapter 3 were two sets of factors controlling the rate of perchlorate formation: mechanistic factors (i.e., chlorate ion concentration, hypochlorite ion concentration, and ionic strength) and environmental factors (i.e., temperature). The results of constant molar-product (of hypochlorite and chlorate ions) experiments showed that sample solutions containing the highest concentration of hypochlorite had a faster rate of perchlorate formation and a greater concentration of perchlorate formed. This strongly suggests that either (1) the order with respect to hypochlorite is higher than one, or (2) the rate of perchlorate formation may be dependent on an additional variable such as ionic strength. Additionally, the data presented in Chapter 3 also suggested a strong temperature dependence for the rate of perchlorate formation. Therefore, in order to elucidate the chemical rate law and develop a "Predictive Model" the following approaches were taken to eliminate possibilities and determine the variables that best correlate with perchlorate formation:

1. Determine the reaction order with respect to hypochlorite and chlorate. Initially, assume the reaction order is one in both hypochlorite and chlorate.

2. If the rate constant of the rate law based on first order in each reactant does not correlate well with concentration, then consider a higher order for one or both reactants. If the order is higher than one, then a second reaction pathway (parallel or consecutive) should be considered. Determine whether a parallel reaction pathway or consecutive reaction pathway can be fitted.

3. Determine what correlations, if any, exist between ionic strength, temperature, and rate of perchlorate formation. In this case, the assumption of first order in hypochlorite and chlorate ions is initially used to convert the rate of perchlorate formation (change in perchlorate concentration per unit time) to the observed rate of formation (k_{obs}, which is the rate of formation normalized to the molar product of hypochlorite ion and chlorate ion concentrations). Only data from experiments conducted at the same, constant temperature are compared.

4. Determine the temperature dependence of the rate of perchlorate formation by using the Eyring Equation. From this, the enthalpy and entropy can be determined and later used to correct for variations in temperature.

5. Develop a model based on the established relationship between prediction of the perchlorate formation rate constant, ionic strength, and temperature.

6. Fit the experimental data using the determined rate constant based on various reaction pathways, and determine which reaction pathway provides the best fit.

DETERMINATION OF THE RATE LAW FOR PERCHLORATE ION FORMATION

Hypochlorite and chlorate ion concentrations were found to have a strong effect on the rate of perchlorate formation. An increase in concentration of either species consistently caused an increase in the rate and final amount of perchlorate formed. Other chemical species, such as bromide, chlorite, and transition metals were identified to have a direct impact on hypochlorite and chlorate, thereby causing changes in concentrations of hypochlorite or chlorate which affected perchlorate formation. Thus, the hypothesis that the formation of the perchlorate ion was a direct result of reactions between hypochlorite and chlorate ions (Equation 3.3, Chapter 3) was assumed correct.

$$OCl^- + ClO_3^- \rightarrow ClO_4^- + Cl^- \qquad \textbf{(3.3)}$$

Given that perchlorate formation was dependent on both concentrations of hypochlorite and chlorate the following rate law was proposed:

$$Rate = \frac{d[ClO_4^-]}{dt} = k_2[OCl^-]^m \times [ClO_3^-]^p \qquad \textbf{(3.4)}$$

A series of experiments were designed to determine the reaction order with respect to hypochlorite and chlorate ions (reported in Chapter 3, Figures 3.1, 3.3). In these experiments, either OCl^- or ClO_3^- concentration was varied while holding the concentration of the other reactant constant. The observed rate of perchlorate formation was then correlated with the concentration of each reactant by taking the natural log of Equation 3.4 to yield Equation 4.1:

$$\ln(Rate) = \ln k_2 + m \ln[OCl^-] + p \ln[ClO_3^-] \qquad \textbf{(4.1)}$$

The second order rate constant (k_2) and the value of the reaction order with respect to OCl^- and ClO_3^- (m and p, respectively) are determined by least squares data fitting. The next several pages are devoted to fitting natural log of the rate of perchlorate formation versus natural log of the chlorate and hypochlorite concentrations.

Order with Respect to Chlorate Ion: $\ln(\frac{dClO_4^-}{dt})$ vs. $\ln [ClO_3^-]$

The order with respect to chlorate was determined by plotting the natural log of the rate of perchlorate formation against the natural log of the chlorate ion concentration in the experiments with constant hypochlorite ion concentration and variable chlorate ion concentration. The slope of the line represents the order with respect to chlorate (p) while the intercept is the sum of $\ln(k_2)$ and m*ln[OCl-] (Equation 4.1). Figure 4.1 (a-d) shows plots of ln(Rate) vs. $\ln[ClO_3^-]$ at different temperatures and incubation lengths. The slope and Pearson correlation coefficients (R^2) across all temperatures investigated are summarized in Table 4.1. As can be seen from Table 4.1, fitting ln[Rate] vs $\ln[ClO_3^-]$ in general produces linear correlation with an average R^2=0.9838, and average slope of 1.05 ± 0.105. This strongly suggests that the order of the reaction is first order with respect to chlorate ion.

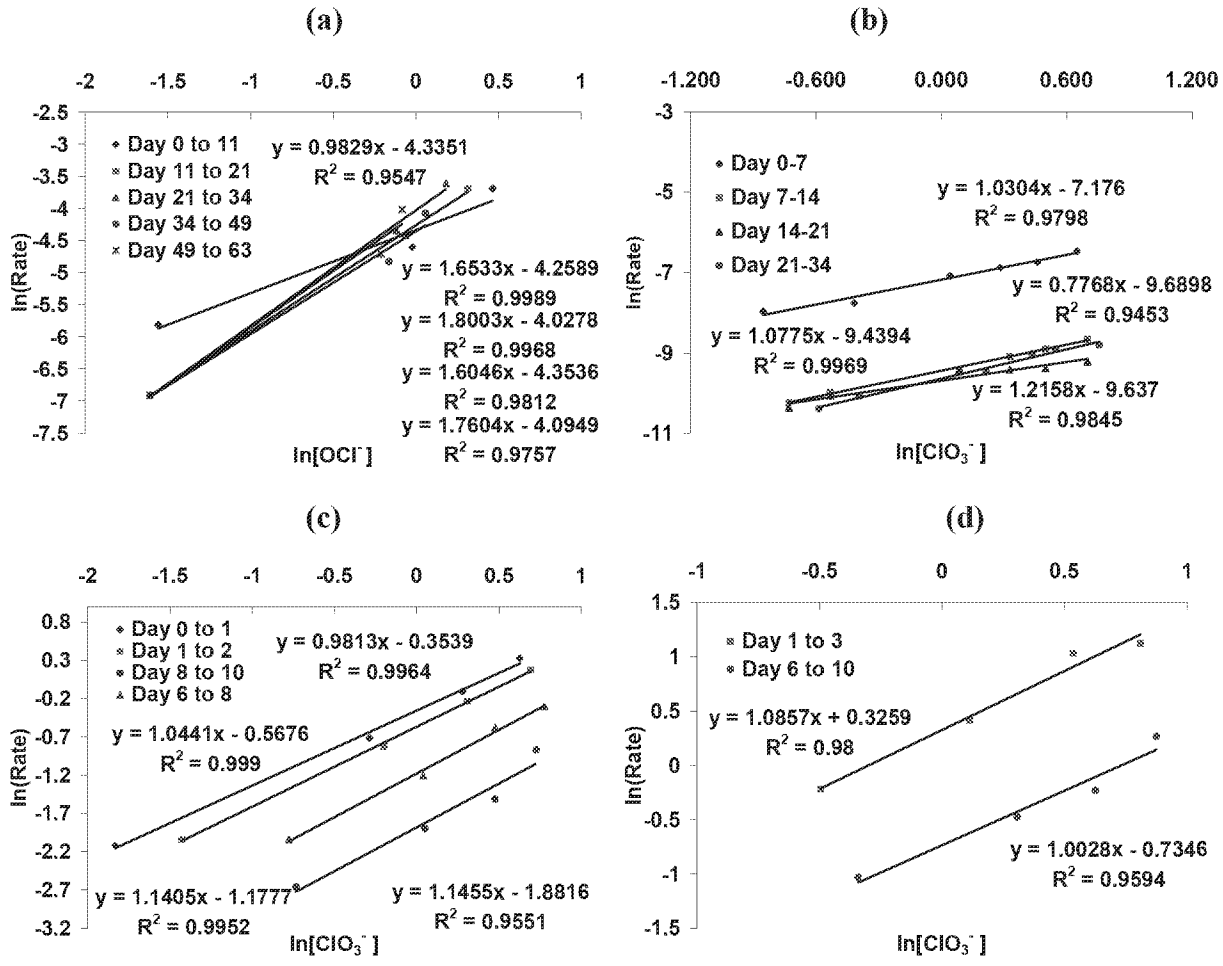

Figure 4.1 Plot of ln(Rate of perchlorate formation) vs. ln[ClO_3^-] at (a) 30 °C, (b) 40 °C, (c) 50 °C, and (d) 75 °C

76	1.003	0.9594
Mean	**1.05 ± 0.105**	**0.9838**

Order with Respect to Hypochlorite Ion: $\ln(\frac{dClO_4^-}{dt})$ vs. ln [ClO_3^-]

The order with respect to hypochlorite was determined by plotting ln[Rate] vs ln[OCl^-] in the set of experiments with constant chlorate ion concentration and variable hypochlorite ion concentration. The slope of the line should represent the order with respect to hypochlorite (*m*) while the intercept is the sum of ln(k_2) and p*ln[ClO_3^-] (Equation 4.1). Figure 4.2 (a-d) shows plots of ln(Rate) vs. ln[OCl^-] at different temperatures and incubation periods. It is immediately evident from the data that the slope varies within individual experiments as well as by temperature and by time. Thus, either the order with respect to hypochlorite is greater than one or another variable is controlling the reaction rate.

Given the disagreement within the data regarding the order with respect to hypochlorite, two explanations were possible: (1) The order with respect to hypochlorite is greater than one due to second reaction pathway or (2) Another variable such as ionic strength was also impacting the rate of perchlorate formation. Thus, while new data (and data already collected) were incorporated into hypothetical considerations of higher order models in hypochlorite (with parallel or consecutive reaction pathways), additional experiments were designed to investigate the effects of ionic strength on perchlorate formation.

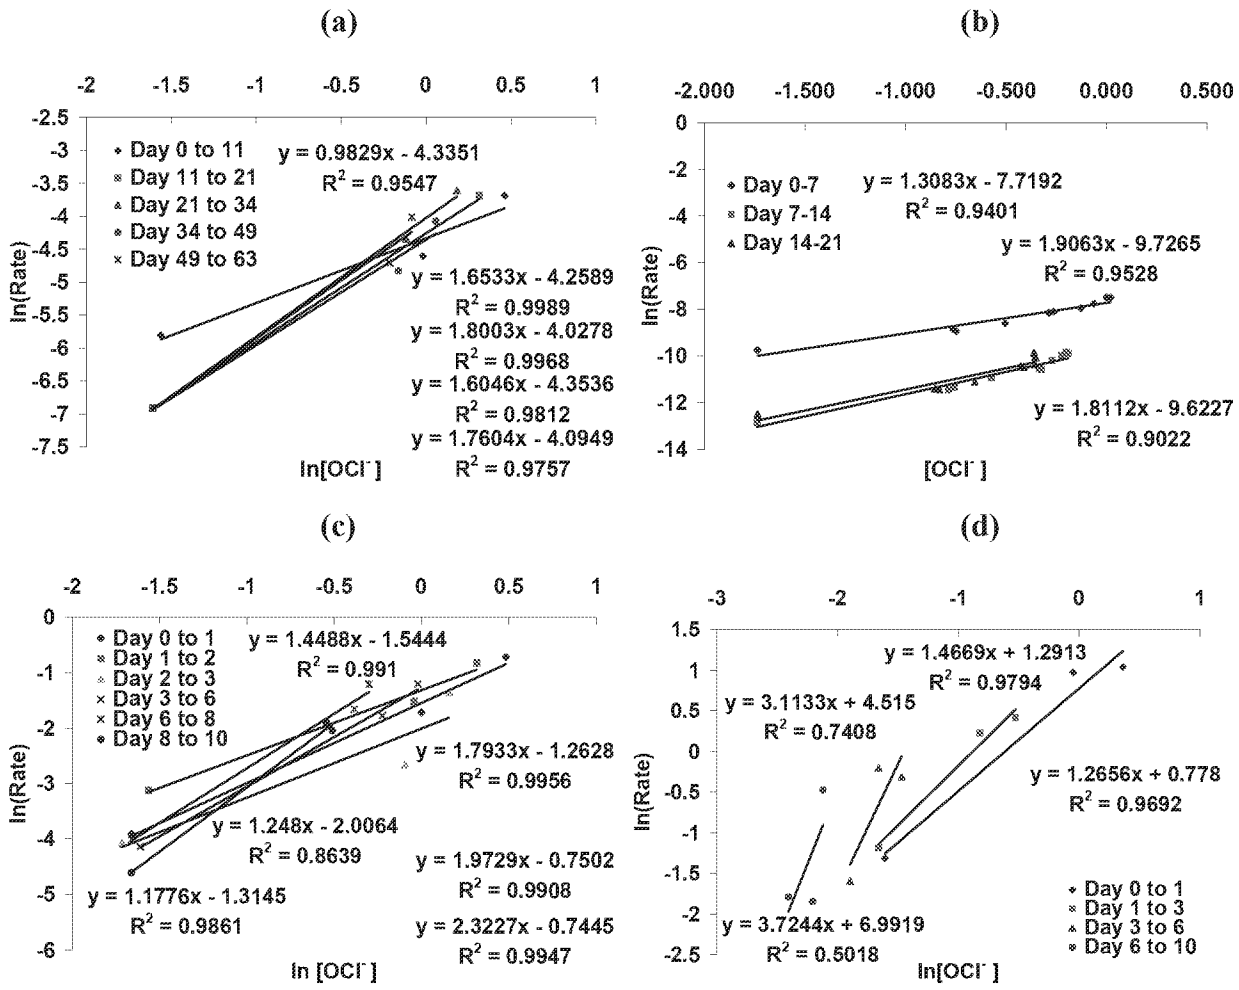

Figure 4.2 Plots of ln(Rate of perchlorate formation) vs. ln [OCl^-] at: (a) 30 °C , (b) 40 °C, (c) 50 °C, and (d) 75 °C

Reaction Order Greater than One with Respect to Hypochlorite: Parallel or Consecutive Reaction Pathways

The variability in the order with respect to hypochlorite, suggested that the order of the perchlorate formation is higher than first order in hypochlorite ion. By taking only the initial rate of perchlorate formation from constant-chlorate-variable-hypochlorite experiments conducted at 75 °C, 50 °C, 40 °C, and 30 °C and plotting that against the log of the hypochlorite ion concentration, the slope of the line is suggestive of a reaction order of 1.6 in hypochlorite (Figure 4.3-a) and 1.0 in chlorate (Figure 4.3-b). Such an empirically-derived rate law is summarized in Equation 4.2 but does not contain any explanation of species involved in perchlorate formation nor does it take into consideration the significant contribution of ionic strength in chlorate formation (Adam and Gordon 1999) or perchlorate formation (Chapter 3).

$$Rate = \frac{d[ClO_4^-]}{dt} = k_{obs}[OCl^-]^{1.6}[ClO_3^-]^1 \qquad \textbf{(4.2)}$$

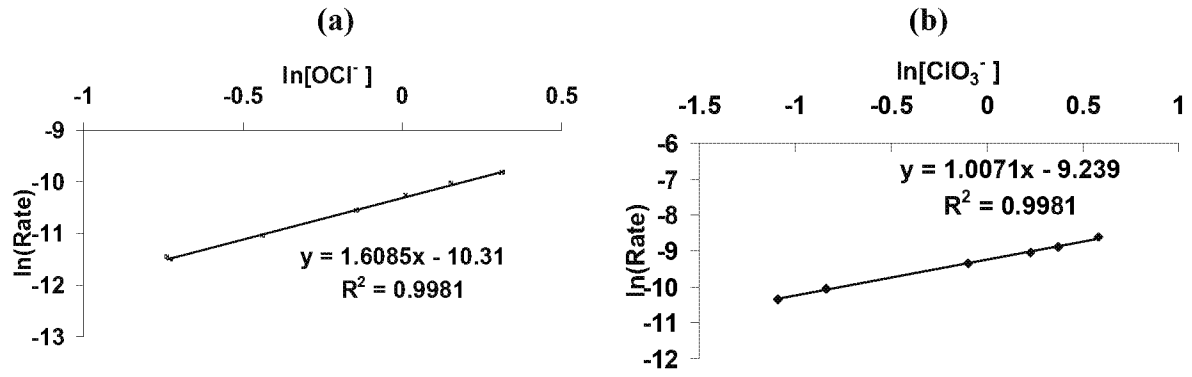

Figure 4.3 Plot of Rate vs ln [OCl^-] (a) and ln[ClO_3^-] (b)

To elucidate the order with respect to hypochlorite further, and to provide more of a mechanistic explanation of the rate of formation, one area explored was the possibility of a second reaction that is second order in hypochlorite. In a parallel reaction, one pathway could be first order in hypochlorite while a second reaction could be second order in hypochlorite. In a consecutive reaction, the order with respect to hypochlorite could be second order, followed by a first order reaction (or vice versa). The hypothetical rate law equations are shown in Equation 4.3 for the parallel reaction mechanism and Equation 4.4 for the consecutive reaction mechanism.

$$Rate = \frac{dClO_4^-}{dt} = k_1[OCl^-]^1[ClO_3^-]^1 + k_2[OCl^-]^2[ClO_3^-]^1 \qquad \textbf{(4.3)}$$

$$Rate = \frac{dClO_4^-}{dt} = \frac{k_a[OCl^-]^2[ClO_3^-]^1}{1 + k_b[OCl^-]^1} \qquad \textbf{(4.4)}$$

Parallel Reactions

In the investigation of a parallel reaction pathway, data from experiments that varied in concentration of hypochlorite but were constant in chlorate can be used to determine the values of k_1 and k_2. First, Equation 4.3 was rearranged by dividing by the molar product of hypochlorite and chlorate to yield Equation 4.5.

$$\frac{Rate}{[OCl^-]^1[ClO_3^-]^1} = k_1 + k_2[OCl^-]^1 \qquad \textbf{(4.5)}$$

By using Equation 4.4, when [Rate/([OCl^-][ClO_3^-])] is plotted vs. [OCl^-], a linear correlation will provide values of k_2 (the slope of the line) and k_1 (the intercept). Example data from the 40 °C

experiment are shown in Figure 4.4. The data shown indicate a reasonable correlation (R^2 = 0.98), but the rate law still does not account for ionic strength effects.

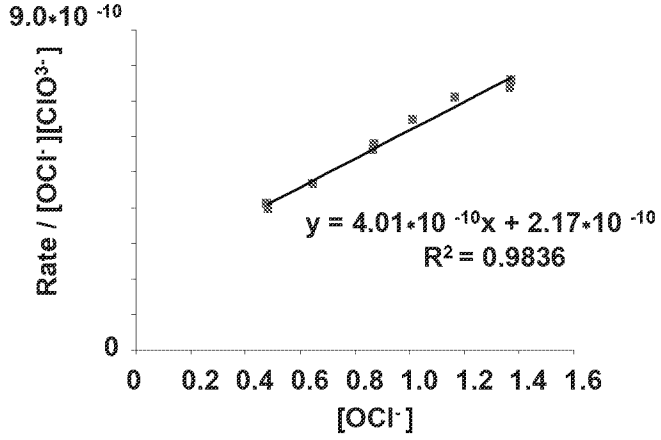

Figure 4.4 Plot of Rate/([OCl^-][ClO_3^-]) vs. [OCl^-] at 40 °C

Consecutive Reactions

In a consecutive reaction pathway, data from experiments that varied in concentration of hypochlorite but were constant in chlorate can also be used to determine the values of k_a and k_b. First, Equation 4.4 was rearranged to isolate hypochlorite, yielding Equation 4.6.

$$\frac{[OCl^-][ClO_3^-]}{Rate} = \frac{1}{k_a[OCl^-]} + \frac{k_b}{k_a} \qquad \textbf{(4.6)}$$

Thus, if ([OCl^-][ClO_3^-])/Rate is plotted against 1/[OCl^-], and the correlation is linear, the slope of the line is $1/k_a$ and the intercept is the product of k_a and k_b. Example data from the 40 °C experiment are shown in Figure 4.5. Again, a reasonable correlation of the data exists (R^2 = 0.98), though it is unclear whether this mechanism fully explains the rate of perchlorate formation, either.

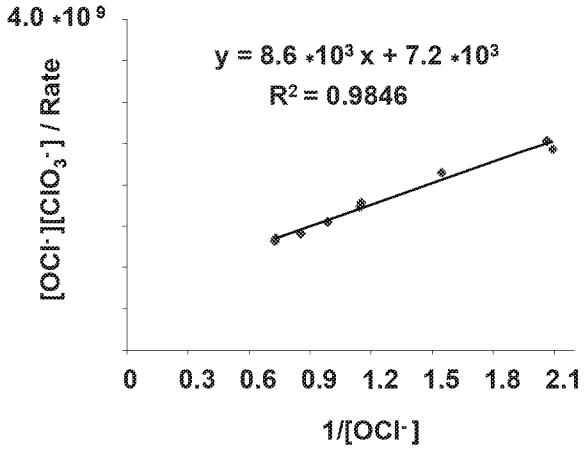

Figure 4.5 Plot of ([OCl⁻][ClO₃⁻])/Rate vs. 1/[OCl⁻] at 40 °C

Ionic Strength Effect on the Observed Rate Constant

While the discussion points mentioned in the previous sections indicate the possibility of the order with respect to hypochlorite being greater than one and that either parallel or consecutive reaction pathways could be used to explain the formation of perchlorate, a simpler explanation could involve the incorporation of ionic strength into a first order reaction in both hypochlorite and chlorate (second order overall). Similar to the parallel and consecutive reaction pathways, ionic strength correlates reasonably well to the rate of perchlorate formation (Figure 4.6). With ionic strength as the simplest explanation for the deviation in observed reaction order, a measure of the variability of ionic strength across experiments was required to further quantify the relationship. Thus, an *a posteriori* measurement of ionic strength for each incubation study sample was made by taking measurements of conductivity and converting them to ionic strength by Equation 2.12. The data are compiled in Table 4.2 for the constant chlorate concentration experiments and Table 4.3 for the constant hypochlorite concentration experiments.

RSD	1.02	7.64	1.26

The variability in ionic strength in the constant chlorate data set (Table 4.2) was at least 3 times higher than that in the constant hypochlorite data set (Table 4.3). These data are easily explained by the fact that the constant chlorate experiments required significant dilution of the hypochlorite solutions while the constant hypochlorite experiments only required addition of sodium chlorate. Thus, the observed variation in the sample matrix set designed to elucidate the order of the perchlorate formation reaction was irrefutably comprised of dissimilar sample matrices. As, such the ionic strength effect must be accounted for before further consideration of higher order reaction pathway.

The first step in quantifying the relationship between ionic strength and the rate of perchlorate formation was to relate the observed rate constant at a given ionic strength to a calculated rate constant at "infinite dilution" or "zero ionic strength" (k_0). The Extended Debye-Hückel Equation, also known as the Davies Equation, can be used to relate the observed rate constant (k_{obs}) to the ionic strength of the solution by Equation 4.7. This equation is also useful for relating rate constants between experiments with different ionic strength as one can determine the theoretical rate constant at "infinite dilution" (k_0 at zero ionic strength).

$$\log(k_{obs}) = 1.02 Z_M Z_N \left(\frac{I^{0.5}}{1 + I^{0.5}} - \beta I \right) + \log(k_0) \qquad \textbf{(4.7)}$$

where,

k_{obs}	=	observed rate constant
k_0	=	rate constant at infinite dilution (zero ionic strength)
Z_M, Z_N	=	charges of individual reactants in rate determining step
β	=	experimentally determined coefficient
I	=	ionic strength (mol/L)

Since the product of $Z_M x Z_N$ = (-1 charge of OCl^-) x (-1 charge of ClO_3^-) = +1, Equation 4.7 becomes Equation 4.8:

$$\log(k_{obs}) = 1.02 \left(\frac{I^{0.5}}{1 + I^{0.5}} - \beta I \right) + \log(k_0) \qquad \textbf{(4.8)}$$

To simplify Equation 4.7 further, an assumption similar to one employed by Adam and Gordon (1999) in the determination of the relationship between the rate constant of hypochlorite decomposition and ionic strength was used: Equations 4.7 and 4.8 contain a "1.02 ($I^{1/2}$ / (1 + $I^{1/2}$)" term that is dominant at low ionic strength, and a 1.02 βI term that dominates at high ionic strength. If both terms are plotted as a function of ionic strength (Figure 4.7), it is evident that the "1.02 ($I^{1/2}$ / (1 + $I^{1/2}$)" term does not change as rapidly as the 1.02 βI term at ionic strength above 1M. Thus, this additional term could be removed from the equations to simplify when working above 1M. Since the majority of experiments performed during this project had an ionic strength in 1-7 M range, this simplification was used. Thus, Equation 4.8 can be further simplified to Equation 4.9.

$$\log(k_{obs}) = 1.02\beta I + \log(k_0) \qquad \textbf{(4.9)}$$

where $\log(k_0)$ is determined experimentally by fitting log (k_{obs}) vs I.

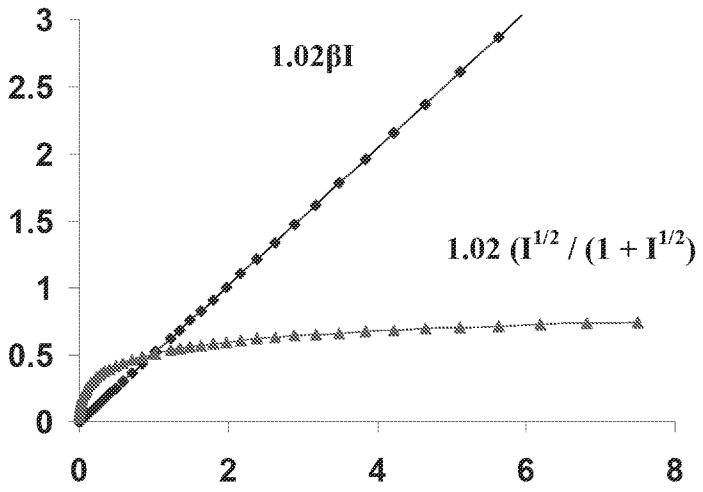

Figure 4.7 Plot of low ionic strength term [1.02 ($I^{1/2}$ / (1 + $I^{1/2}$)] and high ionic strength term [1.02 βI] as a function of ionic strength. The contribution of [1.02 βI] term becomes dominant at high ionic strength. *Assuming coefficient β value of 0.5 as an approximation.

In choosing to explore the ionic strength effect on the rate of perchlorate formation, the decision was made to use the assumption that the reaction was first order in hypochlorite and first order in chlorate in order to calculate an observed rate constant (Equation 4.10). Data from the previous incubation studies were compiled together with the ionic strength measurements and the rate of perchlorate formation was converted to the observed rate constant by dividing the average rate of initial perchlorate ion formation by the initial concentrations of hypochlorite and chlorate ions (Equation 4.10).

$$k_{obs} = \frac{\text{Rate}}{[OCl^-] \times [ClO_3^-]} \qquad \textbf{(4.10)}$$

Figure 4.8 shows the experimentally determined relationship between the rate constant and ionic strength at different temperatures. The dependence of rate constant on ionic strength increases with temperature as can be seen by increase in the slopes of the fitted lines. The slopes of the fitted lines are equal to 1.02βI and the intercepts are equal to log k_0. A summary is given in Table 4.4. The agreement of the slopes of the line between temperatures (6.35% RSD) indicate that (1) ionic strength correlates well with the rate of perchlorate formation and (2) the assumption of first order in both chlorate and hypochlorite is appropriate. Thus, ionic strength and the concentration of chlorate and hypochlorite ions were both incorporated as controlling variables in the rate of perchlorate formation.

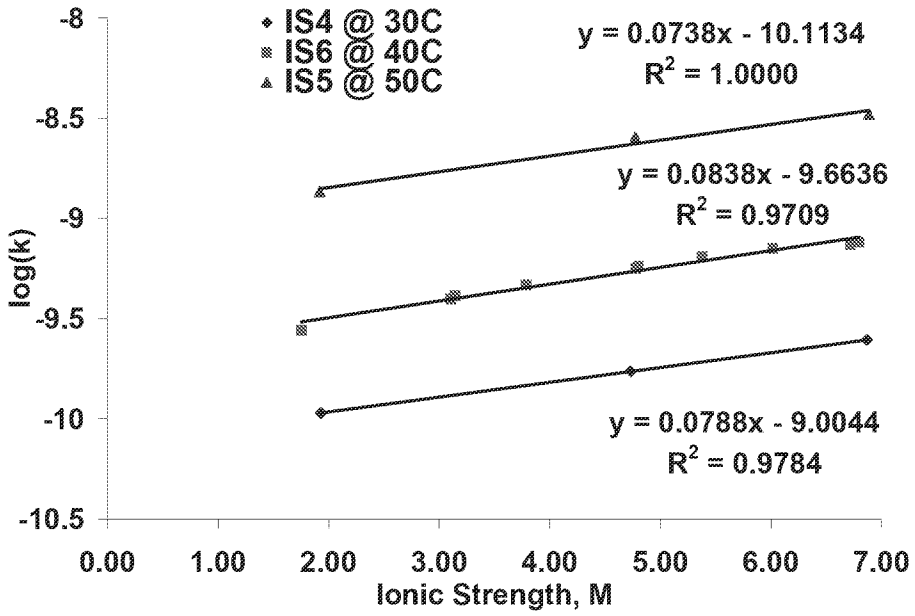

Figure 4.8 Plot of log[k_{obs}] vs. ionic strength of solution

Quantitation of Temperature Effects on the Rate of Perchlorate Formation

In order to combine the dependence of the observed rate constant on ionic strength and temperature, the zero ionic strength rate constant at infinite dilution (k_0) must be related to temperature dependence. Both the Arrhenius and the Eyring equations can be used to describe the temperature dependence of a reaction rate. The Arrhenius equation is applied to the kinetics of gas reactions whereas the Eyring equation (Equation 4.11), which is based on Transition State Theory, can be used for studying kinetics of reactions occurring in liquids.

$$k_0 = \frac{k_b}{h} \times T \times e^{\frac{\Delta S}{R}} \times e^{-\frac{\Delta H}{RT}} \qquad \textbf{(4.11)}$$

k_0	=	calculated from Equation 4.4	
k_b	=	Boltzmann's constant	1.381×10^{-23} J · K^{-1}
h	=	Plank's constant	6.626×10^{-34} J · s
R	=	Gas constant	8.3145 J/mol K
ΔS	=	Entropy of activation	
ΔH	=	Enthalpy of activation	

Taking the log of Equation 4.11 gives:

$$\ln\left(\frac{k_0}{T}\right) = \ln\left(\frac{k_b}{h}\right) + \frac{\Delta S}{R} - \frac{\Delta H}{RT} \qquad \textbf{(4.12)}$$

A plot of $\ln(k_0/T)$ should be a linear function of 1/T, if the data follows Equation 4.12. The slope of the line can be used to calculate ΔH and intercept can be used to calculate ΔS. Figure 4.9 shows a plot of experimentally determined $\ln(k_o/T)$ vs 1/T. Based on three points the R^2 of the line is 0.9832.

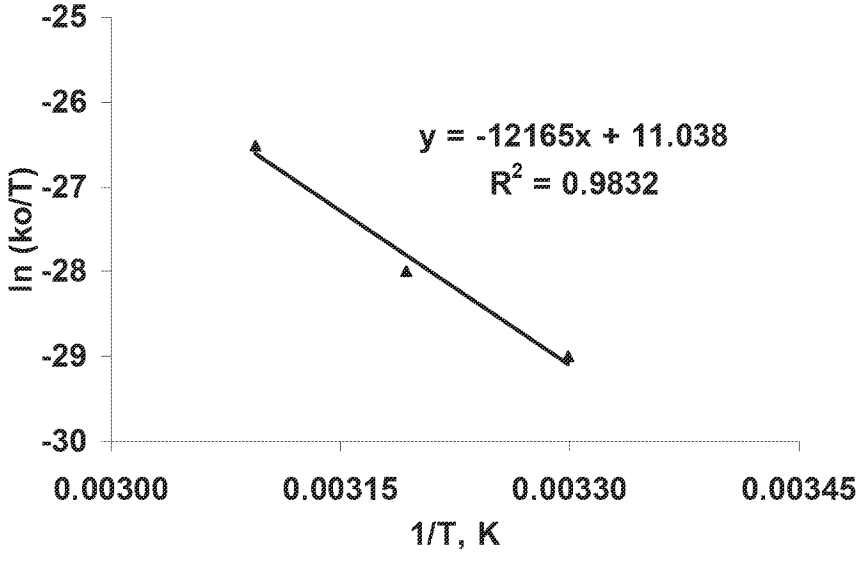

Figure 4.9 Plot of $\ln(k_o/T)$ vs 1/T for commercial hypochlorite solutions

The low Pearson correlation coefficient of 0.983 may indicate that more temperatures need to be studied and/or perhaps some temperature data points need to be repeated in order to reduce the error in the least squares estimation. However, based on the low variation observed in the fitted slopes of 6.4%, shown in Table 4.4 the Pearson correlation coefficient of 0.9832 was deemed satisfactory. The slope of the line equals $\Delta H / R$, where the intercept equals to $\ln(k_b/T) + \Delta S/R$, based on Equation 4.12. Thus, the values of thermodynamic activation parameters for the formation of perchlorate in commercial OCl^- at infinite dilution are $\Delta H = 101$ kJ/mol and $\Delta S = -106$ J/mol · K.

It should be noted that, while the temperature dependence of the reaction is expected to be linear down to zero °C, any interpretation of the model at temperatures below 30 °C (the lowest temperature at which the model was validated) should be limited to qualitative trends only until a time when the model can be validated at lower temperatures. Typically, in order to evaluate the accuracy of a model, a minimum of 1.5 half-lives is required. At temperatures below 30 °C, such validation was not possible given the allotted 11-month time frame of the project.

The Detailed Chemical Rate Law for Perchlorate Formation

Considering the data and results presented in the preceding sections of this Chapter there are three important findings: (1) The observed rate of perchlorate formation is dependent upon the concentration of hypochlorite and chlorate ions and the ionic strength. (2) The observed rate constant (k_{obs}) for perchlorate formation at the temperatures used in the incubation studies is related to ionic strength by a factor of 0.0788 M^{-1} (±0.005 M^{-1} or 6.35%). (3) The rate of perchlorate formation is temperature dependent. A generalized temperature *term* (relating zero ionic strength rate constant to temperature) can be derived from Equation 4.11 by incorporating the known values for ΔH and ΔS (Equation 4.13).

$$k_0 = 2.084\times10^{10}\times T\times e^{\frac{-1.01\times10^5}{RT}}\times e^{\frac{-106}{R}} \qquad \textbf{(4.13)}$$

Thus, substituting a factor of 0.0788 (Table 4.4) for the $1.02\beta I$ term in Equation 4.9 and the demonstrated temperature dependence (Equation 4.13) for the k_0 term in Equation 4.9 yields a quantitative chemical rate law ("Predictive Model") that can be used to calculate the predicted rate constant (k_{calc}) of perchlorate formation at any temperature and ionic strength (Equation 4.14).

$$\log(k_{calc}) = 0.0788(I) + \log\left(2.084\times10^{10}\times T\times e^{\frac{-1.01\times10^5}{RT}}\times e^{\frac{-106}{R}}\right) \qquad \textbf{(4.14)}$$

Thus, the predicted *rate* of perchlorate formation for any stepwise change in hypochlorite and chlorate ion concentrations can be calculated by a rearrangement of Equation 4.10 to yield Equation 4.15. By proxy, the concentration of perchlorate can also be calculated at any time point *provided the concentration of hypochlorite ion and chlorate ion can be predicted using Bleach 2001.*

$$Rate = \frac{dClO_4^-}{dt} = k_{calc} \times [OCl^-]^1 \times [ClO_3^-]^1 \quad \textbf{(4.15)}$$

Using the "Predictive Model" shown in Equation 4.14, calculated rate constants (k_{calc}) for perchlorate formation at specific ionic strength and temperatures were compared to experimentally observed rate constants (k_{obs}) and are summarized in Table 4.5. The percent error was calculated by taking the difference between k_{calc} and k_{obs}, then dividing the difference by k_{obs} and multiplying by 100%. The average variability between observed and predicted rate constants is less than 20% across three temperatures (30 ºC, 40 ºC, and 50ºC) and with ionic strength ranging from 1.8 mol/L to 6.9 mol/L.

Table 4.5
Calculated rate constants vs. observed rate constants at variable ionic strength and temperature

T (ºC)	I (M)	k_{obs} (M^{-1} d^{-1} x 10^6)	k_{calc} (M^{-1} d^{-1} x 10^6)	Percent Error	Average % Error	R^2 (log k vs. I)
30	6.87	21.38	21.76	1.8

50	4.77	219.79	189.46	13.8		
50	1.92	117.24	112.84	3.8	**6.7**	**0.9784**

*R^2 of 1.000 is based on 3 data points only

The agreement between the predicted experimentally determined values, given in Table 4.5, suggests that in fact the determined relationship of the rate constant on ionic strength and temperature given by Equation 4.14 can sufficiently predict the rate constants of perchlorate formation in bulk sodium hypochlorite solutions that have pH 11-13 and ionic strength of 1-7 Molar. Thus, fitting the data using more complex reaction pathways, such as a parallel or consecutive reaction pathway is simply not applicable or practical.

VALIDATION OF THE "PREDICTIVE MODEL"

To further validate the "Predictive Model", Equation 4.14 was used to generate the rate constants needed to calculate the rate of perchlorate formation at different temperatures for several sets of samples that varied in ionic strength. The samples chosen for validation of the "Predictive Model" were bulk hypochlorite solutions used during the various incubation studies. First, *Bleach 2001* (Adam, Gordon, and Pierce 2001) was used to predict the decomposition of hypochlorite and formation of chlorate for each sample. Second, experimentally measured ionic strength, via a conductivity extrapolation, was applied to Equation 4.14 to generate rate constants of perchlorate formation at specific temperatures. Third, the obtained rate constants and the *Bleach 2001* predictions were used to predict perchlorate concentration at multiple time points during the incubation period.

Figures 4.10 and 4.11 show plots of observed and predicted (*Bleach 2001*) decomposition of hypochlorite and formation of chlorate at 30 °C and 40 °C. Figures 4.12 and 4.13 show the measured perchlorate concentrations and those calculated from the "Predictive Model". The predicted concentrations were fitted to a smoothed line, and a fixed 10% error bars were added. The error bars on all figures, unless otherwise stated, are set at a fixed value of 10%.

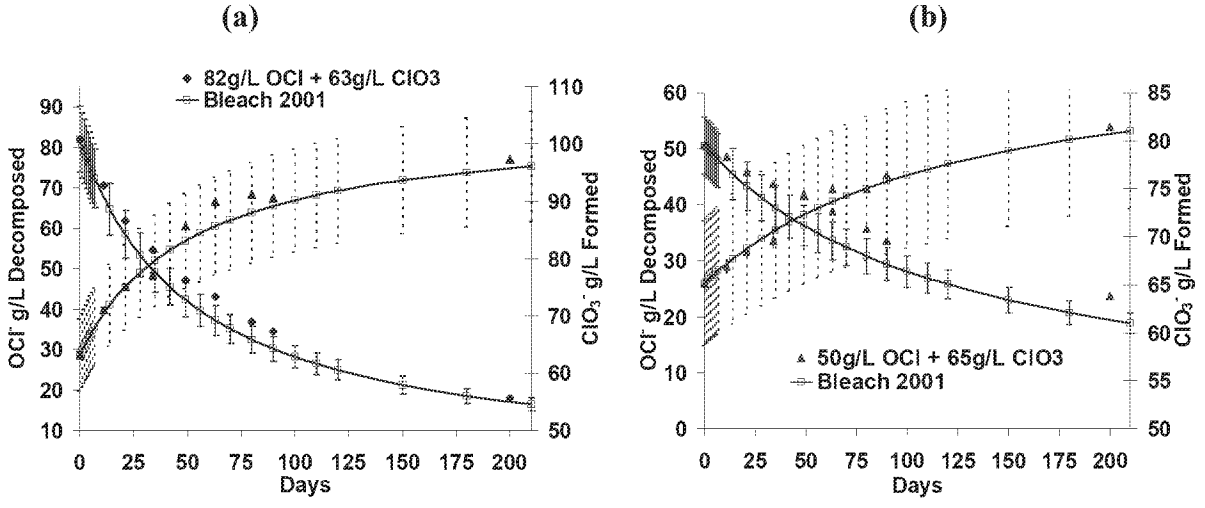

Figure 4.10 Overlaid plot of hypochlorite decomposition and chlorate formation at 30 °C (a) initial concentration of OCl^- = 82g/L (b) Initial concentration of OCl^- = 50g/L

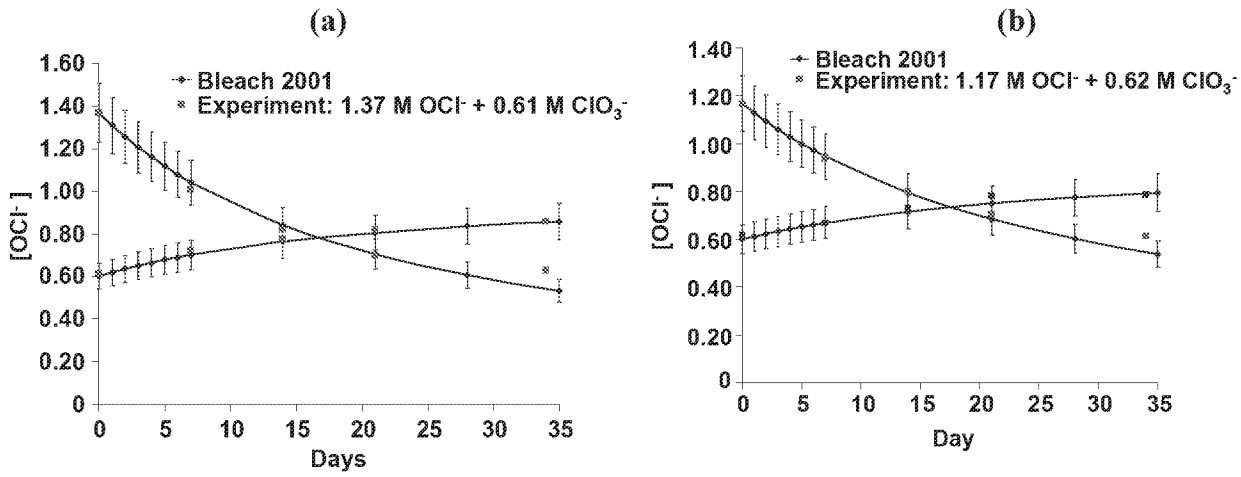

Figure 4.11 Overlaid plot of hypochlorite decomposition and chlorate formation at 40 °C (a) initial concentration of OCl^- = 1.37M (b) Initial concentration of OCl^- = 1.17M

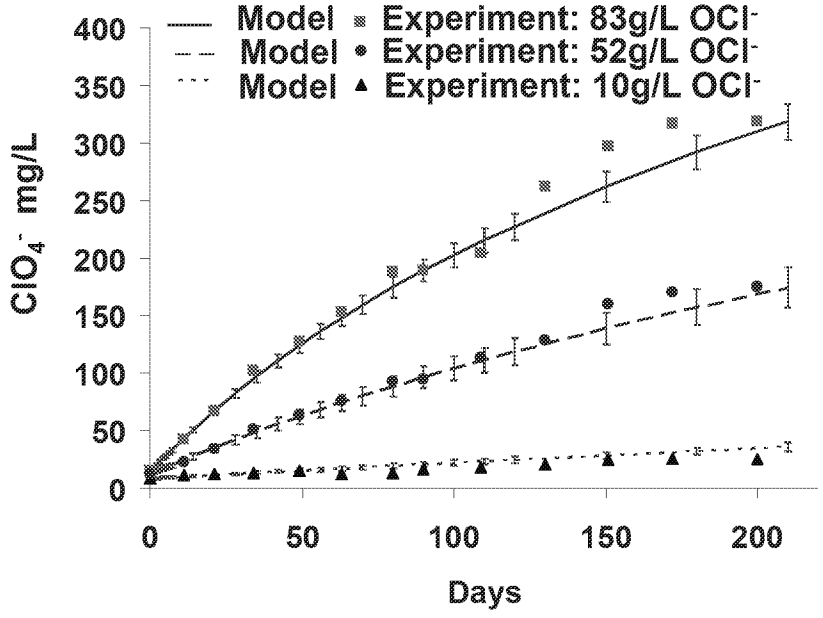

Figure 4.12 Overlaid plot of perchlorate formation experiment vs. predicted at 30 °C

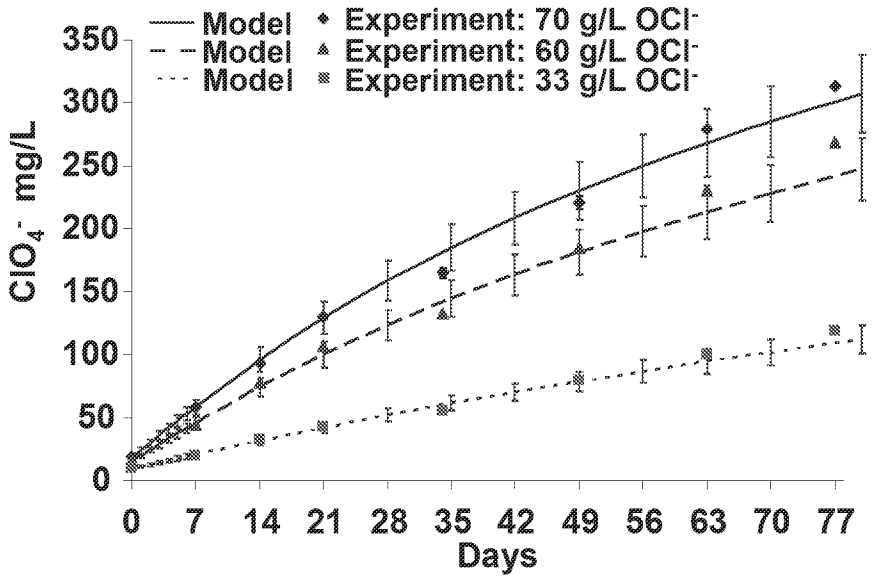

Figure 4.13 Overlaid plot of perchlorate formation experiment vs. predicted at 40 °C

The data shown in Figures 4.12 and 4.13 indicate agreement of 10% or better between observed perchlorate concentration and measured perchlorate concentration in most cases over the entire period of the holding studies. The agreement between experimentally and predicted perchlorate concentrations supports the conclusion that the formation of perchlorate is a second order reaction (first order in hypochlorite and chlorate) that is highly dependent upon ionic strength and temperature. Furthermore, the detailed chemical rate law provided the basis for the "Predictive Model" which not only provides initial rate constants but can also be used in conjunction with *Bleach 2001* to accurately predict perchlorate concentrations as a function of time.

IMPLICATIONS

While the detailed chemical rate law is the key to understanding how factors impact the formation of perchlorate in hypochlorite solutions and can be used to predict perchlorate concentration over time, the primary goal of the "Predictive Model" is really to provide a quantitative platform from which to develop strategies that can be used to minimize perchlorate formation in hypochlorite solutions. As such, a series of hypothetical bulk hypochlorite solutions (starting concentration of 2 M OCl^- or approximately 13% FAC[1]) were used to examine how factors such as dilution and temperature might impact the amount of perchlorate formed in solution over time. Thus, Tables 4.6 – 4.8 were constructed as an aid to understand how the rate of perchlorate formation changes as a function of hypochlorite concentration, temperature, and ionic strength.

The calculations shown in Table 4.6 indicate that dilution by half causes a reduction in rate by a factor of approximately seven and dilution by 10-fold causes reduction in rate of perchlorate formation by a factor of 270. Cooling the hypochlorite solutions also provides

[1] As a point of reference for discussion, a bulk hypochlorite solution of 13% FAC typically equates to approximately 2 M OCl^-, or 103 g/L OCl^-, or 149 g/L NaOCl, or 13.6% NaOCl (depending on the specific gravity).

significant reduction in the rate of perchlorate formation: Cooling by just 5 °C provides approximately a 2-fold reduction in the rate of perchlorate formation, as can be seen in Table 4.7. Preserving hypochlorite from decomposition is also achieved by dilution and cooling. Thus, strategies preserving hypochlorite from decomposition, such as dilution and reduction in temperature, are also the most effective for mitigation of perchlorate formation. Table 4.8 provides a quantitative analysis of how a combined strategy of dilution and temperature reduction can slow the rate of perchlorate formation across a range of scenarios. For example, a dilution of 1:2 and a reduction of storage temperature by 10 °C can provide a 27-fold reduction in the rate of perchlorate formation. A dilution of 1:4 with the same temperature reduction would result in 140 times slower perchlorate formation. Thus, while temperature is important in reducing perchlorate formation, it requires much more cooling to achieve the same effect as simple 1:2 or 1:4 dilutions.

SUMMARY OF INSTRUCTIONS FOR USER APPLICATION OF THE "PREDICTIVE MODEL"

While the creation of a graphical user interface-based computer program for implementation of the predictive model was outside of the scope of this study, there are a few simple steps that can be taken to use the model directly. This section of the Report is designed to provide a simplified step-by-step set of instructions for application of the model. In order to use the predictive model, a copy of the *Bleach 2001* software is required. Such software is available from the Water Research Foundation. Additionally, this discussion assumes that the user will have a basic knowledge and understanding of how to use a spreadsheet software package such as Microsoft Excel and how best to organize data within that program. The steps to use the model are outlined below:

1. The user must know the following information about the hypochlorite solution under consideration:
    a. The initial/starting concentration (in mol/liter) of hypochlorite ion, chlorate ion, and perchlorate ion.
    b. If the concentration of perchlorate is unknown, assume "zero" for simplicity. This will lead to an underestimation of the actual perchlorate concentration but will still be useful for determining impacts of dilution and temperature variation.
    c. Ionic strength (in mol/liter). This should be measured using a conductivity probe and converted to ionic strength using Equation 2.12.
    d. The temperature at which the solution will be stored (in Kelvin).
    e. The pH of the hypochlorite solution.

2. Using *Bleach 2001* input the values for temperature, pH, hypochlorite ion concentration, and chlorate ion concentration. Allow *Bleach 2001* to calculate all other parameters. *Bleach 2001* will return a list of hypochlorite ion and chlorate ion concentrations for a specified number of days. These data should be placed into a separate spreadsheet program such as Microsoft Excel. Using a spreadsheet software package will facilitate copying formulas between worksheet cells, making the calculations simpler to repeat under varying conditions.

3. Use Equation 4.14 to calculate the rate constant (k_{calc}) for the ionic strength and storage temperature of the hypochlorite solution in question. The term "R" is the ideal gas law constant which is 8.314 J/K·mol. The term "I" is the measured ionic strength of the hypochlorite solution (mol/L). The term "T" is temperature in Kelvin (K = °C + 273). The units of the calculated rate constant (k_{calc}) will be in L/mol/second. Note that Equation 4.14 actually return the $\log(k_{calc})$, thus the user must convert to k_{calc}.

4. Convert k_{calc} into a "per day" unit: multiply k_{calc} (L/mol/sec) by a factor of 86,400 (60 seconds × 60 minutes × 24 hours) to convert to k_{calc} (L/mol/day).

5. Next, the predicted rate of perchlorate formation needs to be calculated for every incremental (per day) change in hypochlorite and chlorate ion concentration as predicted from *Bleach 2001*. Therefore, using a spreadsheet software package, Equation 4.15, and the hypochlorite and chlorate ion concentration at each increment of days (e.g., days 1, 2, 3, 5, 10, 25, 50, 100, 200), plug in the value for k_{calc}, $[OCl^-]$, and $[ClO_3^-]$ to predict the rate of perchlorate formation. The units of the rate prediction will be in mol/L/day and represents the change in perchlorate concentration per unit time.

6. Finally, the rate of perchlorate formation needs to be converted to a concentration value. This involves several steps:
    a. Input the initial (measured) concentration of perchlorate ion at day "zero" into a spreadsheet cell associated with time = zero days. If the initial concentration of perchlorate ion is unknown, use zero mol/L.
    b. For each calculated rate, multiply the rate by the number of days and add that to the predicted concentration. For example, to predict the change in perchlorate ion concentration from Day 0 to Day 1, the predicted perchlorate ion concentration at Day 1 = $Rate_{(at\ Day\ 1)} \times 1\ Day + [ClO_4^-]_{(at\ Day\ 0)}$.
    c. For a longer time increment (such as Day 10 to Day 25), simply adjust the number of days: the predicted perchlorate ion concentration at Day 25 = $Rate_{(at\ Day\ 10)} \times 15\ Days + [ClO_4^-]_{(at\ Day\ 10)}$.
    d. Continue step-wise until the perchlorate ion concentration has been calculated to the desired number of days.
    e. To convert from mol/L to µg/L, multiply the molarity of perchlorate by 99.5 g/mol $\times 10^6$ µg/g

SUMMARY

Variation in ionic strength proved to be a significant factor impacting the rate of perchlorate formation. Establishing a relationship between the rate constant based on first order of the reaction in both hypochlorite and chlorate (second order overall) combined with ionic strength at different temperatures allowed predictions of rate constant to be made using the detailed chemical rate law described by Equation 4.14. The predicted values of the rate constant agree reasonably with the experimental values, with percent error of 2.1% for 30 °C, 17.7% for 40 °C and 6.75 for 50 °C. Thus investigation of higher order reaction pathway was not applicable. This "Predictive Model" was used to predict rate constants for hypochlorite solutions varying by ionic strengths, temperatures, and concentration of hypochlorite. The predicted rate constants were used to predict initial rates of perchlorate formation, and thus the effects of dilution, temperature reduction were evaluated and strategies to mitigate perchlorate formation proposed.

CHAPTER 5
MONITORING OF PERHLCORATE AND OTHER CONTAMINANTS IN HYPOCHLORITE SOLUTIONS

APPROACH

Given that sodium hypochlorite solutions contain contaminants such as chlorite, chlorate, perchlorate, and bromate, this portion of the study was designed (1) to examine the differences in contaminant concentration and formation between sources of hypochlorite solutions and (2) to examine the impact of those solutions on finished and distribution system water quality. Eight utilities were asked to provide samples of hypochlorite solutions (if available), to provide raw water, finished water, and distribution system samples, and to provide qualitative information regarding sources of hypochlorite, storage conditions, etc. In cases where distribution system samples were unavailable, simulated distribution system (SDS) studies were performed. Additionally, samples of brine and hypochlorite solutions from 12 on-site generator (OSG) systems made by three different manufacturers were also provided. Duplicate samples were provided from each site/source, one quenched with malonic acid at the utility upon collection, one unquenched but cooled to 4 °C. All of the hypochlorite solutions, brine, and water samples were analyzed for perchlorate, chlorate, hypochlorite, bromate, and dissolved transition metals (Co(II), Cu(II), Fe(III), Ni(II), and Mn(II)). Hypochlorite solution samples were also aged at 50 °C to measure the rate of hypochlorite decomposition and contaminant formation during a 30-day incubation study.

The quantitative data obtained from the analysis of the fresh and aged hypochlorite solution samples was used to assess potential impacts on finished water and to validate the "Predictive Model" developed from the detailed chemical rate law and described in Chapter 4. First, the maximum use level (MUL) approach described by NSF (NSF/ANSI 2005) was used to predict potential impacts on finished water quality. Next, the *Bleach 2001* program (Adam, Gordon, and Pierce 2001) was used to compare measured hypochlorite decomposition and chlorate formation during the incubation study with the predicted decomposition and formation by *Bleach 2001*. By comparing actual and predicted values, some insight into other possible factors (e.g., metal ions) that may have been impacting decomposition was possible. Finally, the predicted daily concentration of hypochlorite and chlorate from *Bleach 2001* was combined with the "Predictive Model" developed in Chapter 4 of this report to predict perchlorate concentration on a daily basis. Comparing the "Predictive Model" perchlorate concentration with the measured concentration of perchlorate in the aged hypochlorite samples provided additional validation of its applicability to bulk hypochlorite solutions other than those used for development of the detailed chemical rate law.

DESCRIPTION OF UTILITIES AND OSG SYSTEMS

As part of this research study, eight utilities agreed to participate by sending hypochlorite and water samples from the treatment process. Of those utilities, 5 used bulk hypochlorite, 2 used OSG hypochlorite, and 1 used chlorine gas. The participating utilities represented six states and two countries: AZ, CA, FL, GA, NV, OH, and Japan. One participating utility (Utility 8) was a wastewater treatment plant that uses bulk hypochlorite for disinfection of water for non-

potable reuse. Utility 8 represents the only wastewater plant incorporated into the study and was chosen as a "challenge" water to determine whether the more complex matrix could impact perchlorate formation in a simulated distribution system study (SDS). The Japanese site (Utility 3) was sampled during the method development stage of the project but was not re-sampled due to recent data regarding perchlorate in Japan (Asami, Kosaka, and Kunikane 2007; Kosaka 2007; Asami, Kosaka, and Kunikane 2009). The relevant utility descriptions are summarized in Table 5.1.

In addition to the utilities that participated in this study, two large suppliers of OSG systems agreed to supply hypochlorite solutions from ten additional OSG locations and/or systems, providing a total of 12 OSG hypochlorite samples including the two from the participating utilities. A description of the OSG systems is provided in Table 5.2. OSG 9 and 10 are cross-referenced with those in Table 5.1. All OSGs tested used an electrolytic conversion of a brine solution to hypochlorite.

Table 5.1
Information on utilities sampled, age of hypochlorite, and water source

Utility	Hypo source	Sampling date	Hypochlorite age	Water source*
Utility 1-A	Bulk	1/21/2009	60% 90 day-old, 40% 7 day-old	SW
Utility 1-B, OSG 9	OSG 9	1/21/2009	2 days since production	SW
Utility 2	Bulk	1/26/2009	34 days	SW
Utility 3	Bulk	Not Sampled	Not Sampled	Japan, SW
Utility 4	Cl_2 Gas	1/20/2009	N/A	GW, Riverbank Filtration
Utility 5	Bulk	1/26/2009	≥ 5 days	GW
Utility 6, OSG 10	OSG 10	1/29/2009	< 1 day	SW
Utility 7	Bulk	2/7/2009	≥ 12 days	OD, SW, GW
Utility 8	Bulk	1/27/2009	1 to 8 days	WW

*Water sources: SW = Surface Water, GW = Groundwater, OD = Ocean Desalination, WW = Tertiary treated wastewater for non-potable reuse

Table 5.2
Description of on-site generators (OSG), identification numbers, and salt source

OSG Model	Anode Material*	OSG Capacity (PPD)	OSG Energy (kWh/lb FAC)	Years of Service	Salt Source
1a	DSA	24	2.0	4	Unknown
1b	DSA	2,000	2.0	10	Unknown
2a	DSA	75	2.0	4	Unknown
2b	DSA	450	2.0	3	Unknown
3	DSA	750	2.0	1	Unknown
4	DSA	300	2.0	2	Unknown
5	DSA	400	2.0	**	>99.7% as NaCl
6	DSA	180	3.5	**	>99.7% as NaCl
7	DSA	20	3.3	**	>99.5% as NaCl
8	DSA	10	5.2	**	>99.5% as NaCl
9	DSA	1200	Unknown	3	>96% as NaCl
10	DSA	2,000	1.6 to 2.0	2.5, 6.5	>99.7% as NaCl

*Dimensionally Stabilized Anode (DSA), likely titanium; **OSG units only used at factory for testing, thus had << 1 year service time; *** No other information provided

Finally, one supplier of calcium hypochlorite agreed to provide freshly manufactured calcium hypochlorite in solid form. Little is known about the formation of perchlorate in solid hypochlorite, but the Project Team wanted to determine if there was perchlorate present from the manufacturing process and whether dissolved calcium hypochlorite would age any differently than sodium hypochlorite. While it is understood that calcium hypochlorite is not commonly stored in dissolved form and is typically used immediately upon dissolution, it was decided that dissolved calcium hypochlorite would be aged as a comparison to determine whether there was some other contaminant (e.g., chloride) that could potentially impact perchlorate formation. Thus, with the utility hypochlorite solutions and OSG samples, calcium hypochlorite was also aged at 50 °C for a period of 30 days using nominal concentrations of 3% and 6% FAC.

RESULTS

Contaminants in Bulk, OSG, and Calcium Hypochlorite Solutions

The concentration of hypochlorite, perchlorate, chlorate, and bromate in the bulk samples for each of the 8 utilities is shown in Table 5.3.

- Only Utility 1-A appeared to have significant impacts on finished water concentration from the perchlorate levels in the bulk hypochlorite. The low FAC concentration at Utility 1-A (compared with other bulk hypochlorite solutions tested) and the high levels of perchlorate and chlorate could be explained by the age of the hypochlorite solution which was a mixture of 90-day old (60%) and 7-day old (40%) bulk hypochlorite.

- None of the utilities were above California's 6 µg/L MCL for perchlorate and only two were above Massachusetts's 2 µg/L MCL.

- Chlorate contamination from the hypochlorite solutions appeared to impact all of the utilities tested. Of those utilities, three had concentrations of chlorate in the finished drinking water above the 800 µg/L notification level in California and an additional utility was at the proposed 200 µg/L action level recommended in CA (Howd 2002).

- Bromate was observed at mg/L levels in all bulk hypochlorite solutions, though none of the utilities tested had finished water concentrations over the 10 µg/L bromate MCL mandated by the US EPA.

Table 5.3
Summary of perchlorate, chlorate, and bromate concentrations in raw water, finished water, and hypochlorite used at participating utility locations

			ClO_4^-			ClO_3^-			BrO_3^-		
Utility	Source	FAC (g/L)	Hypo (µg/L)	Raw (µg/L)	Fin. (µg/L)	Hypo (mg/L)	Raw (mg/L)	Fin. (mg/L)	Hypo (µg/L)	Raw (µg/L)	Fin. (µg/L)
1-A	Bulk	87	14,000	<0.5	3.6	19,000	0.014	0.58	24,000	<0.5	0.5
1-B	OSG 9	6.8	3,500	<0.5	<0.5	480	0.026	1.5	2,700	<0.5	3.6
2	Bulk	150	670	<0.5	<0.5	5,900	0.005	0.019	30,000	<0.5	<0.5
4	Cl_2 Gas	n/a	n/a	<0.5	<0.5	n/a	<0.003	<0.003	n/a	<0.5	<0.5
5	Bulk	120	220	<0.5	<0.5	1,800	0.13	0.20	9,000	1.3	1.4
6	OSG 10	8.7	19	2.0	2.1	380	0.008	0.16	<100	<0.5	1.3
7	Bulk	120	230	<0.5	<0.5	2,400	<0.003	0.13	9,900	<0.5	0.92
8	Bulk	130	2,000	1.6	1.2	8,000	<0.003	0.79	7,700	<0.5	2.6

Hypo = Hypochlorite solution; Raw = Raw water entering the treatment plant; Fin = Finished water leaving treatment plant; Samples analyzed in duplicate measurements, with average % difference for: ClO_4^- 2.0%, BrO_3^- 4.2%, and ClO_3^- 2.5%.

The OSG samples also had high variations in FAC, chlorate, and perchlorate concentrations as shown in Table 5.4. All samples labeled "quenched hypochlorite" were collected at the utility in bottles pre-dosed with malonic acid. Non-quenched samples were cooled to 4 °C and shipped with the quenched samples to the laboratory at SNWA via overnight delivery. Samples were collected directly from the OSG when possible; otherwise they were collected from dosing tanks/day tanks. The solution for OSG 9 was at least 48 hours old when collected and may have been stored at temperatures up to 42 °C. The brine solution and feed water for OSG 9 were at 40 to 42 °C prior to electrolytic conversion.

- Most OSGs had less than 700 µg/L chlorate present in the finished product.

- Bromate concentration ranged from 0.2 mg/L to 6 mg/L. Bromate concentrations are limited by the amount of bromide (which is rapidly converted to bromate in

hypochlorite solutions) and is likely related to the amount of bromide present in the salt and/or feed water used for hypochlorite generation.

- There were no discernable trends in the amount of perchlorate or chlorate formed by any given OSG with respect to energy consumption, OSG production capacity (pounds per day), or actual FAC concentrations.

Table 5.4
Chlorate, bromate, and perchlorate data for quenched and non-quenched samples and the feed brine to the OSG

	Quenched hypochlorite				Non-quenched hypochlorite				Brine

10	450	0.13	19	<0.1	780	0.15	19	8.7	<0.5	<0.1	<2.5

*Sample contaminated, no perchlorate data available for unquenched hypochlorite; **Too much sample was added to the bottle provided with pre-dosed quenching agent, thus quenching was not complete

Transition metal ion concentrations measured for this study were low in most of the bulk hypochlorite (Table 5.5), OSG (Table 5.6), and brine samples (Table 5.7), though Utility 1-A had nickel present at 0.2 mg/L, copper at 0.1 mg/L and iron concentrations approaching 10 mg/L in the hypochlorite solution itself. As metals have been shown in earlier chapters and elsewhere to have a catalytic effect on the decomposition of hypochlorite, the presence of iron and nickel may have been a factor (in addition to age) in the low FAC concentration at Utility 1-A. Regarding the OSG hypochlorite, most brine samples showed higher levels of metal ion contamination relative to the hypochlorite product from the OSG. This difference is likely due to loss of metals to reduction and/or plating on the anode of the electrolytic cell. Current hypochlorite specifications recommend <0.1 mg/L iron and <0.05 mg/L nickel, copper, and cobalt (Gordon and Bubnis 2000). The bulk hypochlorite sampled from Utilities 1-A, 5, 7, and 8 all contained at least one contaminant above the specified levels.

10	N/A	N/A	N/A	N/A	N/A

Transition metal ions were not measured in the calcium hypochlorite solutions. However, bromate, chlorate, and perchlorate were all measured for the 3% and 6% (as FAC) solutions of calcium hypochlorite immediately after mixing with reagent water. The 3% calcium hypochlorite solution had 390 mg/L chlorate, 27 µg/L perchlorate, and 2.4 mg/L bromate for 32 g/L FAC. The 6% calcium hypochlorite solution had 830 mg/L chlorate, 55 µg/L perchlorate, and 5.3 mg/L bromate for 61 g/L FAC.

Given the data described above, a comparison was made by normalizing all of the contaminant concentrations by the concentration of FAC. Table 5.8 was assembled to show a relative contribution (on a mass of contaminant per mg FAC basis) from each hypochlorite solution. Of the comparisons made within the limited data set collected for this project, the only trend that stands out is that the OSGs consistently contribute more bromate per milligram of FAC than the fresh bulk hypochlorite solutions or the two calcium hypochlorite solutions tested. The higher levels of bromate in the OSG solutions are likely a result of bromide in the feed water and/or salt used to make the brine solutions for electrolysis. Current NSF/ANSI 60 standards recommend no more than 0.5 µg BrO_3^- per mg FAC (NSF/ANSI 2005) in hypochlorite solutions. Based on this limit, three OSG solutions exceed the recommendation and an additional two OSGs approached the limit (0.48 µg BrO_3^- per mg FAC). Neither the calcium hypochlorite sample nor any of the bulk hypochlorite solutions exceeded the current bromate standard. Furthermore, only OSGs 5-8 and OSG 10 used a salt with greater than 99.5% purity (as NaCl), a fact reflected in the lowest overall bromate concentrations. Thus, these data support the use of high quality, low-bromide salts for hypochlorite generation, though further investigations detailing specific recommendations should be performed.

Other than the bromate observation, there are no consistent trends and contaminant concentrations vary widely within and between brands, hypochlorite sources, and production methods. Thus, from this limited data set collected during this project, there does not appear to be a straightforward way to determine what type of *freshly prepared* hypochlorite solution (OSG, bulk, or calcium) would result in the lowest mass loading of contaminants into the finished drinking water which is consistent with OSG and bulk hypochlorite data reported elsewhere (Asami, Kosaka, and Kunikane 2009).

Table 5.8
Relative contribution of specific contaminants on a per-mass-FAC basis

		Concentration in hypochlorite solutions				Mass of contaminant added per mg FAC

Contaminant Concentrations in Distribution System and SDS Samples

The concentration of perchlorate, chlorate, and bromate was also measured in the distribution system samples in order to determine whether there was any additional chlorate, perchlorate, or bromate formation. In the case of Utility 2, a SDS study was used instead of collecting actual distribution system samples. Distribution system sampling locations were targeted to give a median residence time and a maximum residence time for each utility. Based on the model developed in Chapter 4 and the considerations of hypochlorite ion concentration, temperature, pH, and ionic strength it was not expected that any appreciable formation of chlorate, perchlorate, or bromate would be observed. The results of the distribution system sampling and SDS studies are shown in Table 5.9.

Table 5.9
Perchlorate, chlorate, and bromate concentrations in finished waters and distribution system samples

Utility	Res. time A (hrs)	Res. time B (hrs)	ClO_4^- Fin. (µg/L)	ClO_4^- Dist. A (µg/L)	ClO_4^- Dist. B (µg/L)	ClO_3^- Fin. (mg/L)	ClO_3^- Dist. A (mg/L)	ClO_3^- Dist. B (mg/L)	BrO_3^- Fin. (µg/L)	BrO_3^- Dist. A (µg/L)	BrO_3^- Dist. B (µg/L)

* SDS conducted on wastewater samples instead of collecting actual distribution system samples—sample A had free chlorine residual with no ammonia while sample B had excess ammonia present and thus free chlorine was converted entirely to chloramines

In all cases except Utility 1-A, the concentration of contaminants did not increase in the distribution system. The difficulty in using grab samples from distribution system is that the hypochlorite solution used to disinfect the water is constantly changing and experiences turnover from new shipments and/or on-site generation. Thus, in order to assess behavior of chlorate, perchlorate, and bromate in distribution systems an in-depth study with more sampling sites (and distribution systems) combined with temporal observations over a period of several months is suggested as a future research direction.

Holding Studies for Bulk, OSG, and Calcium Hypochlorite Solutions

Each of the unquenched OSG solutions collected for this study was held at 50 °C for a period of 30 days while periodic aliquots of the solution were collected for analysis of ionic strength, pH, and concentration of hypochlorite, chlorate, perchlorate, and bromate. Data for the oxyhalides were grouped by manufacturer and graphed against holding time (Figures 5.1, 5.2, and 5.3). As expected, samples with high initial hypochlorite concentrations (e.g., OSG 1a and OSG3, Figure 5.1) also showed higher overall perchlorate formation relative to starting concentration and those with low initial hypochlorite concentration (e.g., OSG 4, Figure 5.1) showed the lowest overall perchlorate formation relative to the starting concentration. Measurements of bromate concentration had a high degree of variability because sample dilutions were made to target chlorate and perchlorate; thus, bromate analysis was not optimized for utility OSG and bulk hypochlorite holding study and the data are not shown. However, bromate concentrations in all OSG and bulk hypochlorite samples did not appear to suggest a trend of increasing or decreasing concentration. Such observation is supported in the bromide/bromate studies discussed in Chapter 3 (most bromate formation is likely to occur during on-site generation or very shortly thereafter).

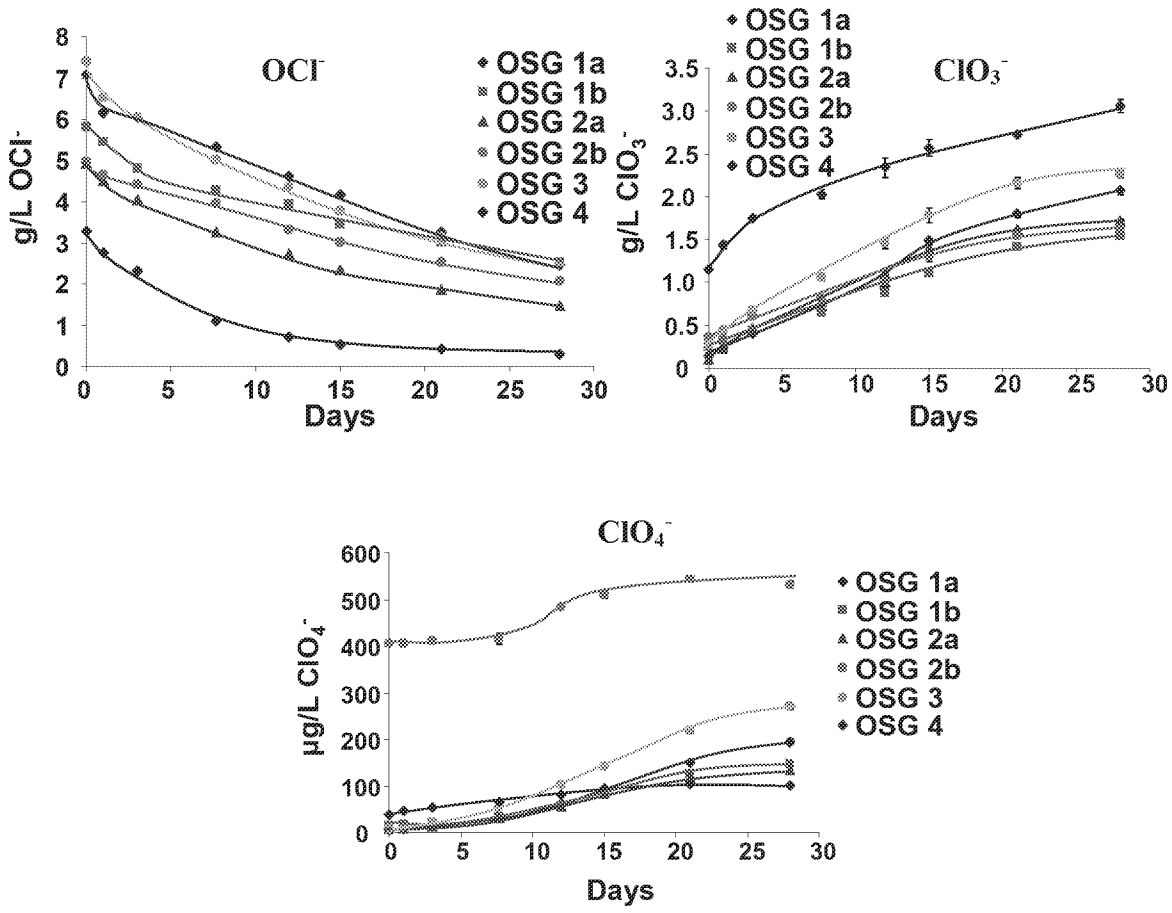

Figure 5.1 Hypochlorite, chlorate, and perchlorate concentrations during 50 °C holding study for six OSG samples from the same OSG manufacturer (different models)

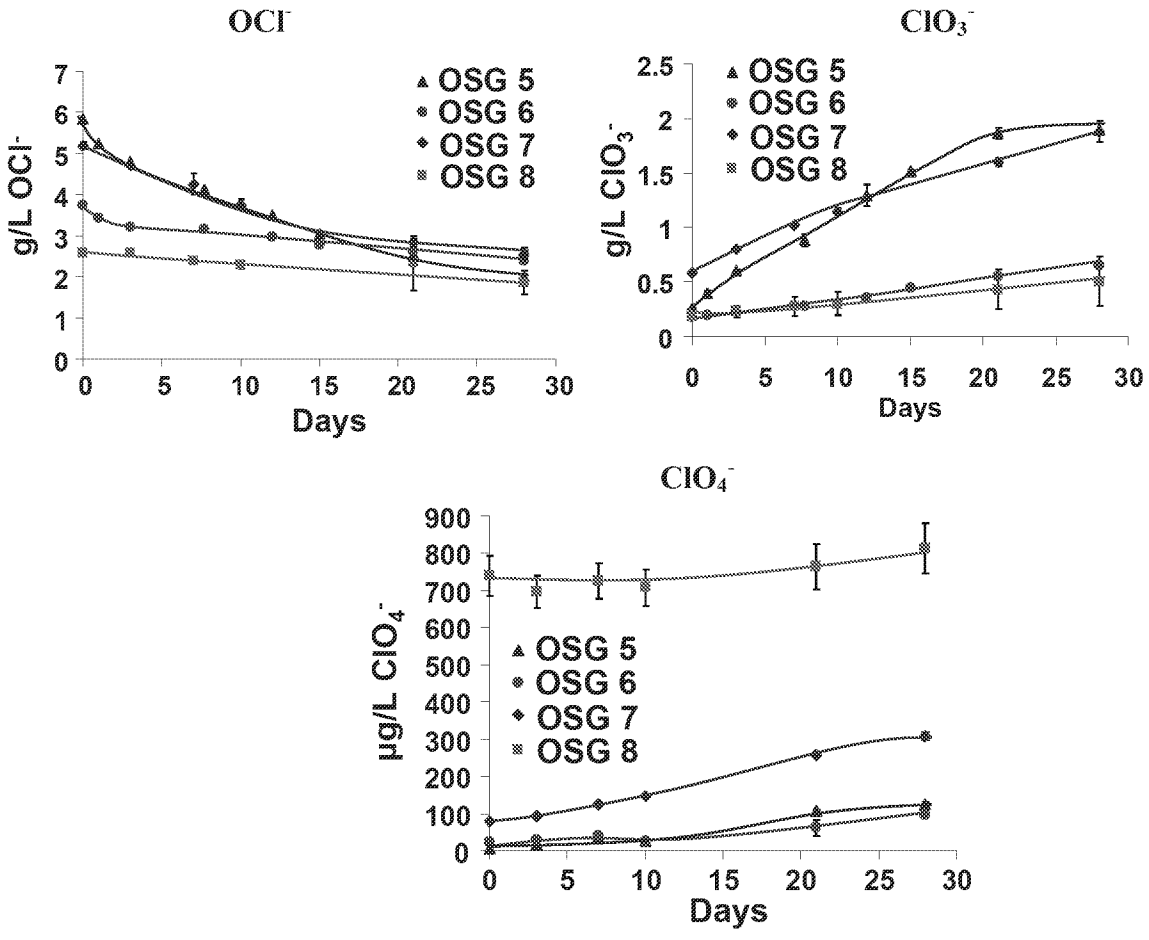

Figure 5.2 Hypochlorite, chlorate, and perchlorate concentrations during 50 °C holding study for 4 OSG samples from the same OSG manufacturer (different models)

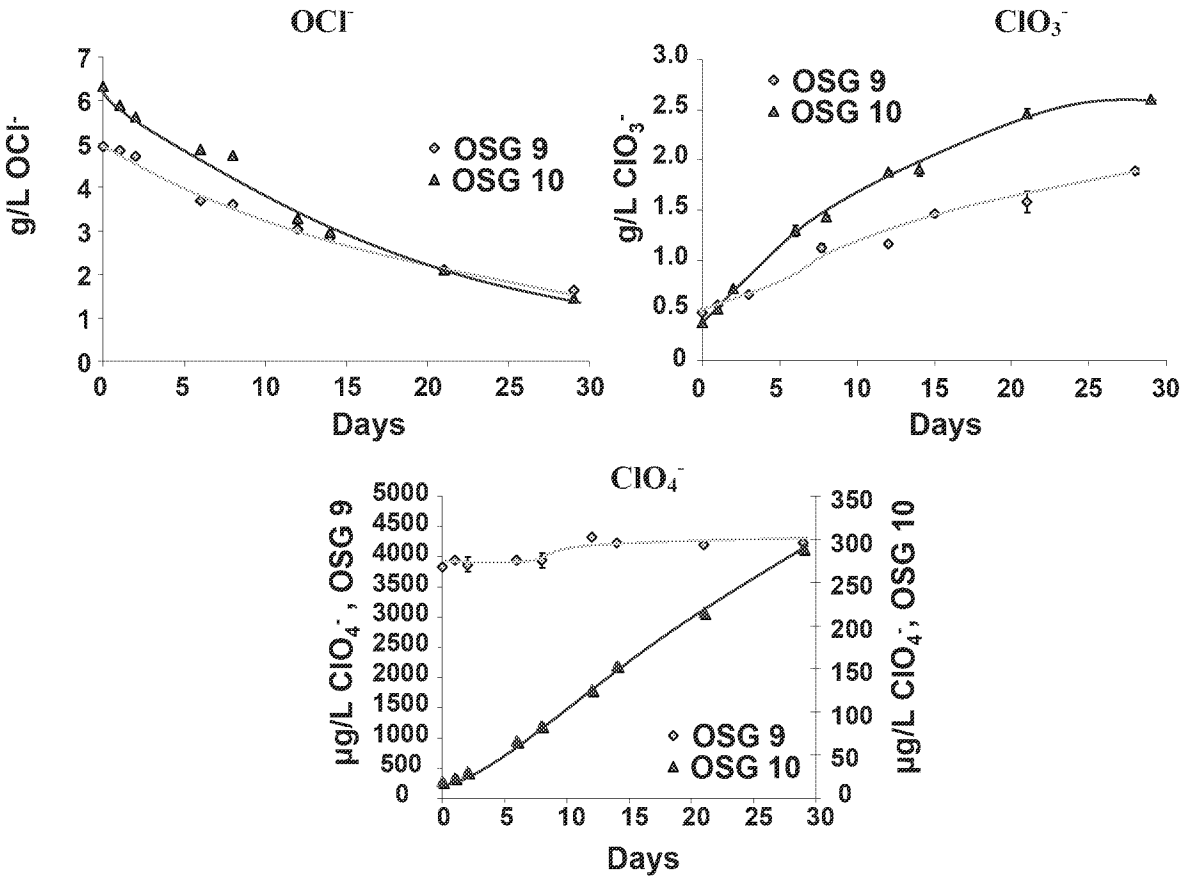

Figure 5.3 Hypochlorite, chlorate, and perchlorate concentrations during 50 °C holding study for the two utility-provided OSG samples

The hypochlorite samples from the utilities were similarly aged at 50 °C and analyzed for changes in hypochlorite, chlorate, perchlorate, and bromate concentrations (Figure 5.4). In all cases a higher initial hypochlorite concentration corresponded to higher rate of chlorate and perchlorate formation. Another interesting observation is the relative magnitude of perchlorate formation in the OSG samples versus the bulk hypochlorite samples. There is significantly less chlorate and perchlorate formation in the aging OSG samples than the aging bulk hypochlorite samples, a fact easily explained by the difference in starting concentration of hypochlorite and predicted by the reaction kinetics.

Similar to the bulk and OSG hypochlorite solutions, the two calcium hypochlorite solutions (3% and 6% FAC) were aged at 50 °C and 60 °C. The data from these two incubation studies are summarized in Figure 5.5. Upon examination of the data there were no major deviations from the trends observed in the bulk and OSG hypochlorite solutions: Increased temperature and increased starting concentration of hypochlorite both increased the rate of chlorate and perchlorate formation.

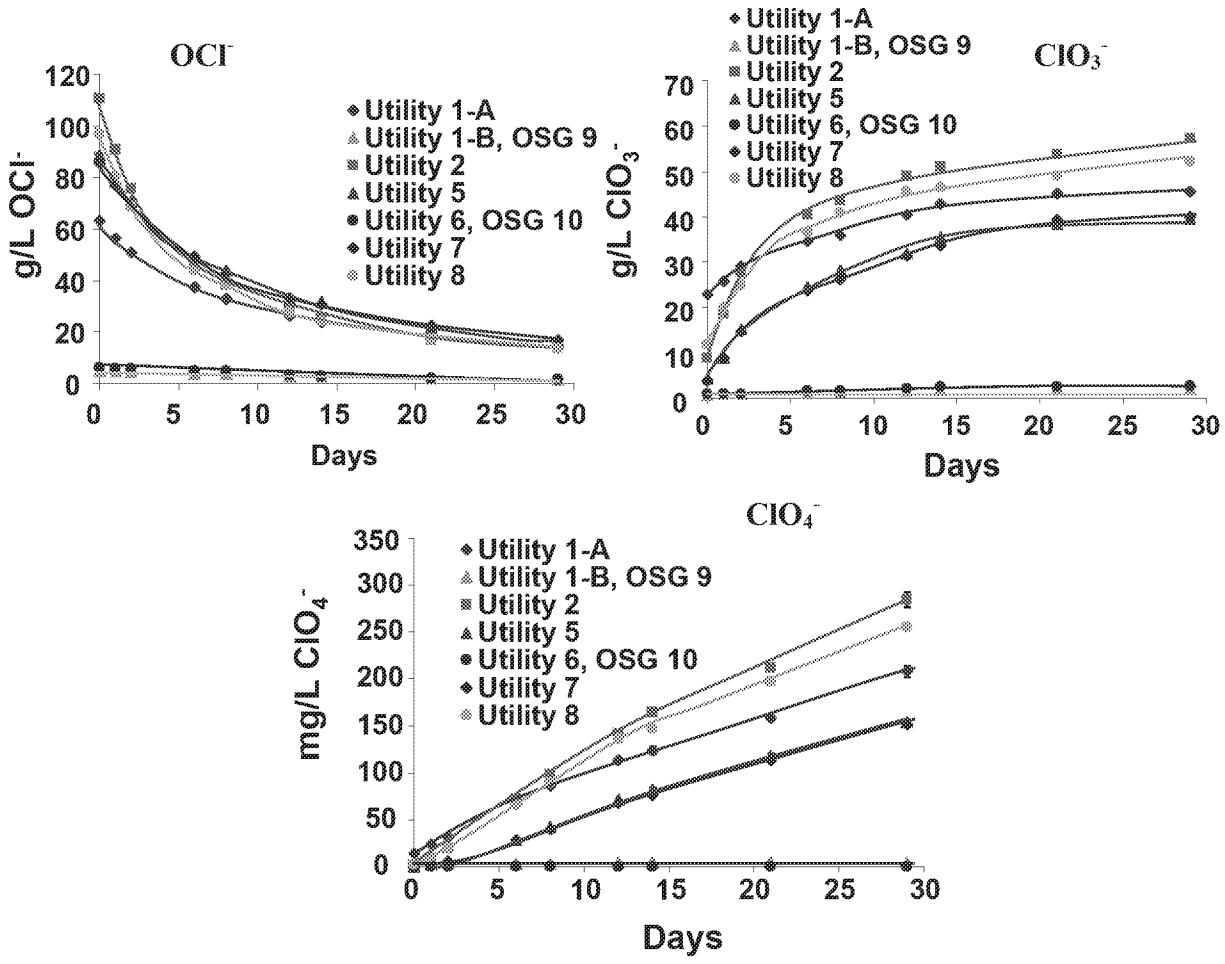

Figure 5.4 Hypochlorite, chlorate, and perchlorate concentrations during 50 °C holding study for all Utility hypochlorite samples

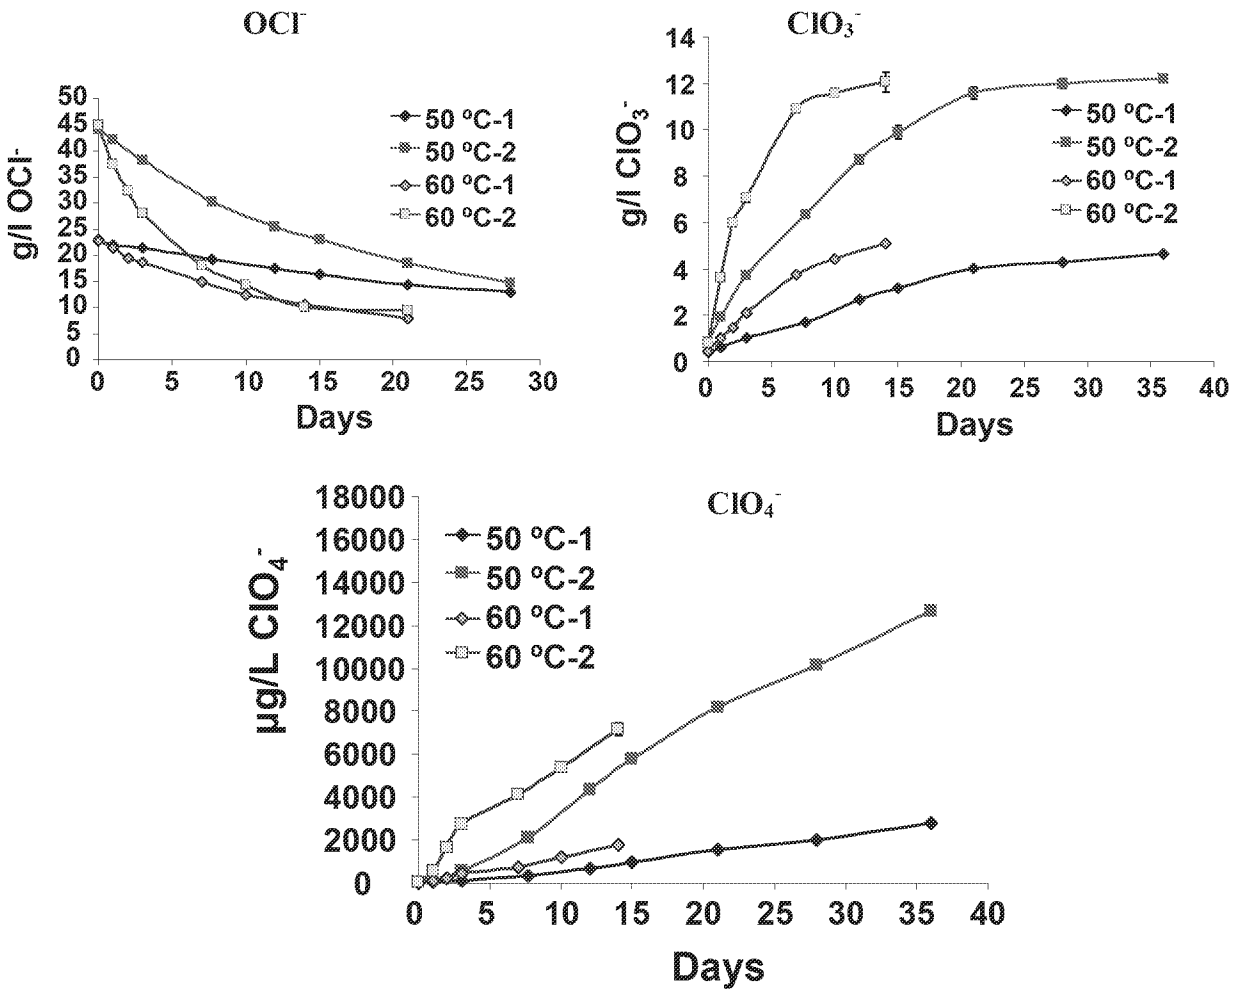

Figure 5.5 Calcium hypochlorite solutions aged at 50 °C and 60 °C with 3% FAC (Cal Hypo 1: 50 °C-1, 60 °C -1) and 6% FAC (Cal Hypo 2: 50 °C-2, 60 °C -2)

Comparison of Measured vs. Predicted Concentration using MUL

The MUL of 10 mg/L was used to estimate the maximum amount of contaminants that could be dosed into the finished water via hypochlorite addition. The calculation of MUL followed the equations listed below and relied upon the measured concentration of specific contaminants (e.g., chlorate, perchlorate, bromate) in the hypochlorite to be dosed into the water plus the concentration of each contaminant in the raw water:

$$\text{Volume}_{\text{hypo dosed}} = \frac{10\,\text{mg/L} \times 1\,\text{L}}{\text{FAC}_{\text{hypo dosed}}\,(\text{mg/L})} \qquad \textbf{(5.1)}$$

$$\text{Max. Conc.}_{\text{MUL,10}} = \frac{\text{Volume}_{\text{hypo dosed}} \times [\text{Contaminant}]_{\text{hypo dosed}}}{1\text{L}} + [\text{Contaminant}]_{\text{raw water}} \qquad \textbf{(5.2)}$$

The maximum expected concentrations of each contaminant based on the MUL approach are listed in Table 5.10. In most cases, the MUL calculated concentrations in the finished water did not match the measured finished water concentrations of chlorate, perchlorate, or bromate though they did provide a conservative estimate. The premise behind the MUL is that it provides for a conservative calculation by *overestimating* the concentration of a contaminant in the finished water by assuming the maximum amount of hypochlorite that would be used at any given facility. While this is a reasonable approach, it is limited in its predictive ability because it does not take into consideration other potential sources of contaminants (e.g., oxidation of bromide to bromate during ozonation) or sinks of contaminants (e.g., ion exchange sites on filter media). Underestimation of contaminant concentrations by >20% occurred 5 times (once for perchlorate, twice for chlorate, twice for bromate). Such observations are consistent with attempts published elsewhere at using injection ratios (similar to MUL but using actual dosing quantities) to predict finished water concentrations of chlorate and perchlorate (Asami, Kosaka, and Kunikane 2007; Asami, Kosaka, and Kunikane 2009). Thus, it is not clear whether using the MUL would be a good tool to predict actual contaminant concentrations in drinking water nor would it be beneficial to use as a "normalization" technique as suggested elsewhere (Greiner, et al. 2008). However, if combined with an understanding of the treatment process at any given facility it may be able to provide a reasonable estimation of maximum expected contaminant concentrations.

Table 5.10

Measured vs. Predicted Concentrations of OCl^- and ClO_3^- in Hypochlorite using *Bleach 2001*

The *Bleach 2001* (Adam, Gordon, and Pierce 2001) model was applied to the aged utility bulk hypochlorite samples for verification that hypochlorite decomposition and chlorate formation was occurring as expected. Four of the five Utility bulk hypochlorite samples were selected for use in this modeling exercise. OSG hypochlorite samples were not used in this exercise as they typically have pH values in the range 9 – 10; the *Bleach 2001* model does not predict below pH 11 because the recommendation for utilities is to store liquid hypochlorite at pH 11 – 13. Thus, running a simulation of OSG hypochlorite decomposition was not applicable. The starting concentration, pH, and holding temperature for the bulk hypochlorite solutions are summarized in Table 5.11. Figure 5.6 shows overlaid plots of hypochlorite decomposition and chlorate formation of measured vs. predicted concentrations for four Utility bulk hypochlorite samples.

Table 5.11
Initial concentrations, pH, and temperature values entered into *Bleach 2001*

Utility	pH	OCl^- (g/L)	ClO_3^- (g/L)	Temperature (°C)
1-A	12.84	63.1	22.8	50
2	13.25	110.7	8.73	50
5	12.90	89.0	4.37	50
8	13.11	96.7	11.6	50

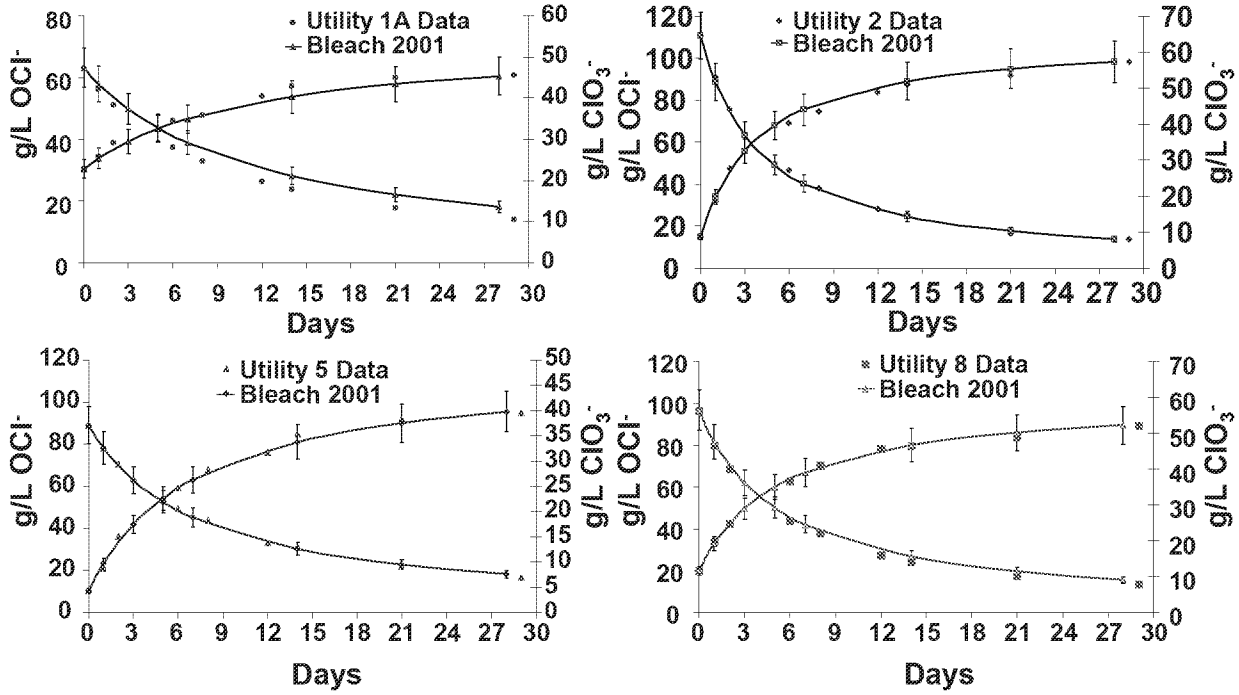

Figure 5.6 Measured vs. predicted concentrations of OCl^- and ClO_3^- in hypochlorite using *Bleach 2001:* Utility 1A, 2, 5, and 8 aged at 50 °C; Error bars are 10% of predicted value

In general, the measured decomposition of sodium hypochlorite samples from the utilities showed excellent agreement (within 5 to 10 %) with the *Bleach 2001* predicted decomposition with the exception of Utility 1-A differing by up to 25%. The plot of the Utility 1-A sample in Figure 5.6 shows that hypochlorite decomposed faster than expected, possibly resulting from the presence of iron at 9.2 mg/L, copper at 0.1 mg/L, and nickel at 0.2 mg/L (Table 5.5) in the hypochlorite solution. Otherwise, the agreement between measured concentrations and predicted concentrations was acceptable. Therefore, considering that the chemical model for predicting perchlorate concentration over time requires an input of predicted hypochlorite and chlorate concentrations, it was determined that *Bleach 2001* could be used to generate those predicted concentrations for use in perchlorate modeling.

Measured vs. Predicted Concentrations of ClO_4^- in Hypochlorite using the "Predictive Model"

The "Predictive Model" from the detailed chemical rate law of perchlorate formation described in Chapter 4 of this report was also applied to the aged bulk hypochlorite samples selected for *Bleach 2001* testing. This application of the "Predictive Model" was used in order to validate its ability to predict perchlorate concentrations in hypochlorite solutions other than those used to develop the model. As an additional exercise, the rate of perchlorate formation and the observed rate constant were calculated for each hypochlorite solution and are summarized in Table 5.12. As seen, the rate of perchlorate formation appears to be impacted by a combination of ionic strength, concentration of hypochlorite, and concentration of chlorate, indicating that each factor is indeed important to include in the "Predictive Model".

Table 5.12
Observed rate and rate constant of perchlorate formation in bulk sodium hypochlorite solutions received from participating utilities

Utility	pH	[OCl-] (mol/L)	[ClO3-] (mol/L)	I (mol/L)	Observed *Rate (x 10^{-6})	**k_{obs} (x 10^{-6})
1-A	12.84	1.226	0.228	5.74	100	363
2	13.25	2.152	0.071	6.47	76	499
5	12.9	1.729	0.022	4.86	19	506
7	13.13	1.661	0.029	4.95	21	427
8	13.11	1.879	0.096	6.26	78	429

*Rate in units of mol ClO_4^- / L / d; **k in units of L / mol ClO_4^- / d
(Utilities 1-B and 6 were OSG samples; Utility 3 was not sampled; Utility 4 used Cl_2 gas)

Comparing the measured concentration of perchlorate over time with the predicted perchlorate concentration provides the best evidence of the validity of the "Predictive Model". Figure 5.7 shows overlaid plots of average measured concentration of perchlorate over time vs. predicted concentration in bulk hypochlorite samples. The error bars in Figure 5.7 have been arbitrarily set at ± 10%. The formation of perchlorate in most samples was predicted to within ± 10% of the actual values. This demonstrates that the "Predictive Model" is a useful way to approximate the formation of perchlorate in bulk hypochlorite solutions. Moreover, this exercise demonstrates that the "Predictive Model" can be used to make specific recommendations to

utilities based on predicted behavior that will assist in minimizing perchlorate formation during storage.

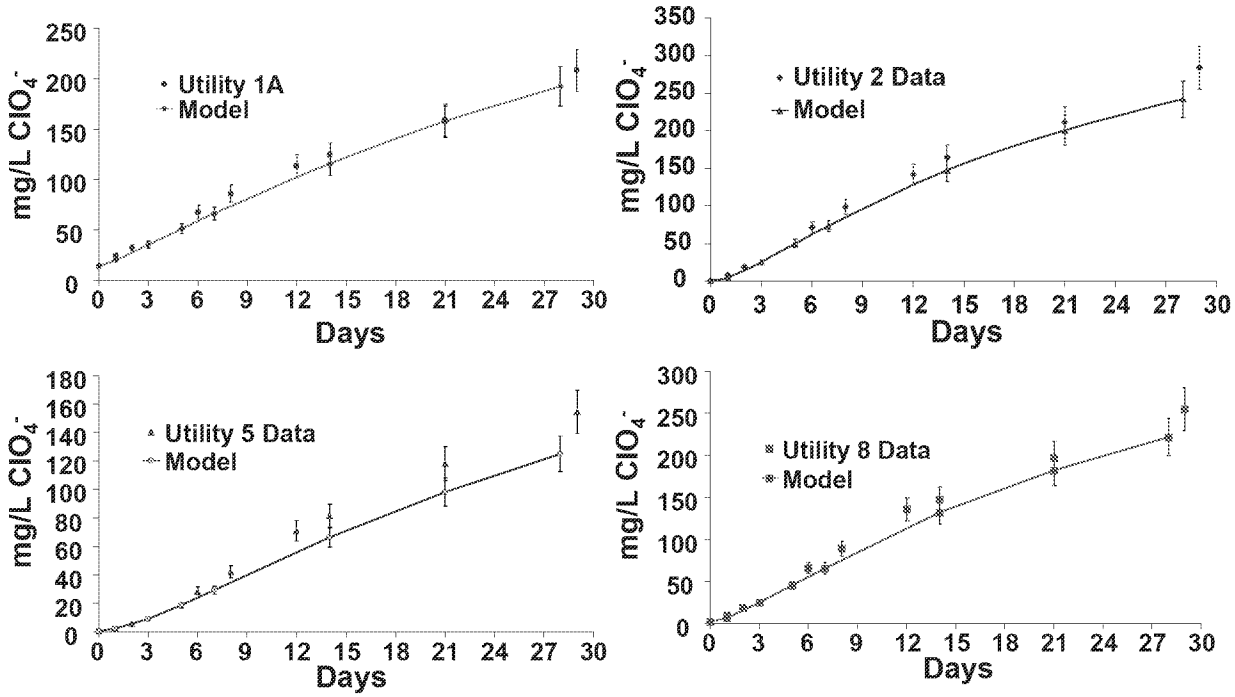

Figure 5.7 Measured vs. predicted concentrations of ClO_4^- in hypochlorite using the Predictive Model: Utility 1, 2, 5, and 8 aged at 50 °C; Error bars are +/- 10%

Finally, in a demonstration of the importance of the "master variables" (ionic strength and concentration of chlorate and hypochlorite), the observed rate of perchlorate formation in each of the bulk hypochlorite, OSG, and calcium hypochlorite was plotted against ionic strength (Figure 5.8) and the molar product (Figure 5.9). Table 5.13 lists the observed rate and rate constants for the OSG and calcium hypochlorite solutions. While the correlation was reasonable for the constant molar product, a significant amount of variability was introduced with the OSG solutions, likely a function of their low pH range (pH 8.8 to 9.8). When the OSG samples are removed (Figures 5.10 and 5.11), a much better correlation (as reflected by the R^2 values) is observed between the observed rate and ionic strength and the observed rate and molar product. The remaining variability in the ionic strength plot (Figure 5.11) may be explained by the use of a surrogate for ionic strength (i.e., conductivity) rather than the true ionic strength of the solution.

Table 5.13
Observed rate and rate constants of perchlorate formation in OSG hypochlorite and calcium hypochlorite solutions

	I (mol/L)	pH	[OCl-] (mol/L)	[ClO3-] (mol/L)	Observed *Rate ($\times 10^{-9}$)	**k_{obs} ($\times 10^{-6}$)

SUMMARY

In summary, the detailed chemical rate law (i.e., "Predictive Model") can be applied to bulk sodium hypochlorite solutions in conjunction with *Bleach 2001* to predict perchlorate formation over time at various temperatures and ionic strength. The model is only applicable to bulk sodium hypochlorite in pH 11-13 range due to the design of *Bleach 2001* working only within the specifications for bulk hypochlorite solutions. At the high temperature selected for aging the bulk hypochlorite samples (50 °C), the "Predictive Model" was able in 3 out of 4 cases to predict actual perchlorate concentrations within 10% of the measured value. Furthermore, observed rates of perchlorate formation in bulk hypochlorite and calcium hypochlorite solutions correlated well with ionic strength and the molar product of hypochlorite and chlorate.

The errors in correlation and prediction observed could be due to the use of a surrogate (i.e., conductivity) for ionic strength instead of true ionic strength. The only way to determine the "true" ionic strength would be to measure the concentration of each cation and anion in the solution and then sum their individual concentrations into a combined ionic molarity. Such an undertaking would be impractical at best for an individual utility wanting to estimate what impact different storage scenarios would have on perchlorate formation. Thus, in bulk hypochlorite solutions that vary widely in quality and starting concentration of each contaminant, using conductivity as a surrogate provides an appropriate and useful surrogate for ionic strength. Furthermore, the model has demonstrated its ability to predict the *trends* of perchlorate formation which, from a utility perspective, is the most useful information to guide the decision making about how best to store bulk hypochlorite solutions.

CHAPTER 6
CONCLUSIONS AND SUMMARY

DISCUSSION

In the first part of this study, two methods were validated for the analysis of perchlorate and chlorate in hypochlorite solutions: titration and LC-MS/MS. The titration method was better suited for use with concentrated (>5% FAC) hypochlorite solutions while the LC-MS/MS method was better suited for use with lower concentration (<5%) hypochlorite and water samples. Bromate was quantified using LC-MS/MS and transition metals were quantified using ICP-MS. Malonic acid was found to be the most reliable and appropriate quenching agent for use in the study, providing no measurable interference in analysis, no problems associated with storage, and no major safety issues associated with shipping, handling, and the quenching reaction itself.

The methods developed in the early stages of the study were used to investigate factors impacting the rate of formation of perchlorate and bromate in hypochlorite solutions. Bromate was found to form within one to two days of introduction of bromide into hypochlorite solutions. Furthermore, bulk hypochlorite and OSG samples received from utilities showed little-to-no additional bromate formation. Thus, the data suggest that nearly all bromate is formed during manufacture or shortly thereafter. Perchlorate formation, on the other hand, was slow enough to measure and was impacted by several sets of factors: (1) Direct (mechanistic) factors including hypochlorite ion concentration, chlorate ion concentration, and ionic strength. (2) Indirect factors including the presence of metal ions and the presence of bromide ion. (3) Environmental factors including pH and temperature. While it is possible to argue that pH is really a mechanistic factor and that ionic strength is really an environmental factor, their effects were categorized as such to simplify discussion of the detailed chemical rate law. Bromide and metal ions were found to impact the formation of perchlorate indirectly by enhancing the loss of hypochlorite, either through decomposition (catalyzed by metals) or formation of bromate. The effect of pH was important, but in the pH 11 – 13 range was not shown to be a major factor in perchlorate formation.

After separating the factors impacting the rate of perchlorate formation, a detailed chemical rate law describing the dependence of perchlorate formation on ionic strength, hypochlorite ion concentration, chlorate ion concentration, and temperature was developed. While initial data indicated the rate of perchlorate formation may have been greater than second order and a result of parallel or consecutive mechanisms, ionic strength turned out to be the "master variable" controlling the reaction rate. As such, the formation of perchlorate is first order in hypochlorite and chlorate ion concentration and is highly dependent upon ionic strength and temperature. Thus, the detailed chemical rate law was used as a "Predictive Model" to predict perchlorate concentration to within 10% of the measured perchlorate concentration in multiple bulk hypochlorite samples aged at different temperatures for up to 200 days. Furthermore, the "Predictive Model" was then used to develop a set of quantitative recommendations for utilities to use to minimize the amount of perchlorate formation in stored bulk hypochlorite solutions. It should be noted, however, that given the time limitation of the study, the model was not validated on real samples below 30 °C. Thus, any predictions below 30 °C should be limited to a qualitative assessment of how dilution and temperature changes impact

perchlorate formation rather than an exact prediction of the actual concentration of perchlorate expected.

Finally, a set of 5 bulk hypochlorite solutions, 12 OSG hypochlorite solutions, and one calcium hypochlorite sample was obtained for contaminant analysis and quantification and was used in a holding study to examine the rate of perchlorate formation in each solution. All samples tested had measurable concentrations of chlorate, perchlorate, and bromate. No specific conclusions could be made regarding differences in contaminant concentrations in bulk, OSG, and calcium hypochlorite solutions. There did appear to be, however, a link between salt quality and bromate concentration in OSG samples, suggesting that a salt of a higher purity (in this study, >99.5% as NaCl) may be useful for reducing the amount of bromate in the hypochlorite product. However, this trend needs to be further investigated before a specific recommendation on salt purity and maximum levels of bromide can be quantified. When the various solutions were aged, good correlation was observed between the rate of perchlorate formation, the concentration of hypochlorite and chlorate ions, and ionic strength. Furthermore, the "Predictive Model" was able to predict perchlorate formation in the commercial bulk hypochlorite samples to within 20% of the measured concentration for up to 28 days at 50 °C.

RECOMMENDATIONS

Based on the findings presented in this report, several key factors have been identified that impact the formation of perchlorate, bromate, and other contaminants in hypochlorite solutions. The major factors impacting perchlorate formation parallel those previously described for reducing the decomposition of hypochlorite: temperature, ionic strength, concentration, and pH. By using the information gathered during this study and by applying the "Predictive Model" to hypothetical liquid hypochlorite storage scenarios, several quantitative and qualitative recommendations can be made:

a. Dilute stored hypochlorite solutions upon delivery: The decomposition of hypochlorite and subsequent formation of chlorate and perchlorate is dependent upon hypochlorite concentration and ionic strength. Higher ionic strength and hypochlorite concentration will drive the reaction towards a greater production of chlorate and perchlorate while also increasing the rate of decomposition of hypochlorite. By diluting a 2 molar hypochlorite solution by a factor of 2, the rate of perchlorate formation decreases by a factor of 7 due to the combination of concentration and ionic strength effects A four-fold dilution of a hypochlorite solution will decrease the rate of formation by 36. A ten-fold dilution of a hypochlorite solution will decrease the rate of perchlorate formation by a factor of 270.

b. Store the hypochlorite solutions at lower temperatures: Higher temperatures speed up the chemical decomposition of hypochlorite and the subsequent formation of chlorate and perchlorate. Every 5 °C reduction in storage temperature will reduce the rate of perchlorate formation by a factor of approximately 2.

c. Control the pH of stored hypochlorite solutions at pH 11 – 13, even after dilution: Storage of concentrated hypochlorite solutions at pH values lower than 11 is not recommended due to rapid decomposition of hypochlorite ion/hypochlorous acid and the consequent formation of chlorate even though this reduces the amount of

perchlorate formed. When the pH is higher than 13, perchlorate formation is enhanced due to the ionic strength effect. As such, utilities should continue to insist that manufacturer specifications include pH control in the range of 11 to 13. Given the typical pH range of OSG hypochlorite (pH 9 to 10), such solutions should be used as soon as possible after manufacture and should not be stored for more than 1-2 days.

d. Control the removal of transition metal ions by purchasing filtered hypochlorite solutions and by using low-metal ion concentration feed water for the OSG systems: The presence of transition metal ions results in an increased degradation rate of hypochlorite. While this degradation is concomitant with reduced perchlorate formation, the FAC concentration is also reduced, forcing a utility to use a higher volume of a hypochlorite solution which results in higher mass loading of contaminants such as perchlorate, chlorate, and bromate.

e. Use fresh hypochlorite solutions when possible: Over time, hypochlorite will naturally decompose to produce oxygen, chlorate, and perchlorate. Less storage time will minimize the formation of these contaminants in the hypochlorite solution. A fresh hypochlorite solution will also contain a higher concentration of hypochlorite, thereby reducing the amount of solution required to obtain the target chlorine residual. Again, higher hypochlorite concentration in a fresh hypochlorite solution will correspond to lower concentrations of contaminants dosed.

f. For utilities using OSG hypochlorite, use a low-bromide salt to minimize the amount of bromide present in the brine: Bromate formation will occur rapidly in hypochlorite solutions in the presence of bromide. By controlling the amount of bromide in the salt and source water used for on-site generation, bromate formation can be minimized.

If a utility were to combine dilution with temperature reduction, a significant impact on hypochlorite decomposition and perchlorate formation would be observed. For example, as described in Chapter 4 if a utility were to dilute a 13% bulk hypochlorite solution by a factor of 2 and also reduce the storage temperature by 10 °C, the result would be 16 times less hypochlorite decomposition and 27 times less perchlorate formation than if the hypochlorite were stored at ambient temperatures undiluted.

Another interpretation of the results of this study is through seasonal trends. If, for example, a utility experienced average bulk hypochlorite storage temperatures of 10 °C in the winter and 35 °C in the summer, the rate of perchlorate formation for 13% hypochlorite would be nearly 18 times faster in the summer. In other words, in winter that utility could expect the concentration of perchlorate concentration to increase by a factor of 10 in approximately 3 months; in summer it would increase by a factor of 10 in only 5 days. Had the hypochlorite solution been diluted by a factor of 2, the same increase in perchlorate concentration would take one month in summer and 20 months (assuming, for example, an average temperature of 10 °C) in winter. Therefore, in order to minimize the amount of perchlorate formation in hypochlorite solutions, a combination of dilution and temperature control is recommended.

FUTURE WORK

While the "Predictive Model" is appropriate for use in bulk hypochlorite solutions, it would be interesting to build in a pH dependence to assist with predictions for OSG hypochlorite which may have pH values in the range of 9 to 10. Also, according to Adam and Gordon (1999), some chloride ion-specific dependence exists within the mechanism of chlorate formation. The direct impact of chloride ion formation (other than in its use to increase ionic strength) was not investigated. Thus, future studies examining the impact of chloride ion on perchlorate formation may be investigated. Furthermore, ionic strength was measured by a surrogate, conductivity, and thus does not reflect the "true" ionic strength of the solution. The detailed chemical rate law incorporates the measured "ionic strength", but may benefit from the incorporation of the "true" ionic strength. As such, future studies are also recommended which may address this issue. The relationship between salt purity and bromate formation during OSG production of hypochlorite needs to be quantified and should be investigated more thoroughly. Finally, in order to assess the behavior of chlorate, perchlorate, and bromate in distribution systems an in-depth study with more sampling sites (and distribution systems) combined with temporal observations over a period of several months is suggested as a future research direction. Such information may indicate whether any contaminant violations could occur in distribution systems with high temperatures and long residence times.

Thank you Eric & Lisa – The attached contain a very few edits/comments. And then, these are ready to go to OW for review. Regarding the outreach plan, continue to pursue the discussions with ASDWA and AWWA as we discussed and agreed to with Dave. However, I'm not sure that we can say these reports will be released soon, maybe it is better to say that there is the potential for them to be issued in the near term.

Thanks much,
Jennifer

Hi Lisa,

We got new information from the MD system. There was some misunderstanding with the information request but here is the latest.

The treatment plant at chapel hill was recently taken off line and it was replaced with new productions wells and treatment plant which started operations in January 27, 2020. Please see the new language that I have incorporated in the revised document below.

"EPA contacted the Chapel Hill System in January 2020. Water system personnel indicated that the Chapel Hill WFP was taken off line and it was replaced with a new treatment plant and five new production wells. The new treatment plant started operations on January 27, 2020. System personnel also indicated that monitoring was conducted in November 2019 and the analysis shows that perchlorate was not detected in either the source well water or the finished water."

Thanks
Sam

Thanks Sam.
Do we know exactly what the contractor asked each PWS? Based on this response: **EPA contacted the Chapel Hill System in January 2020. Water system personnel indicated that no follow-up/updated monitoring data for perchlorate is available.** It appears we only asked about monitoring…did the contractor ask about any changes in source water and/or treatment too?

Thanks,
Lisa

Hi Sam,
We need to develop a couple additional options.
1. Dave has suggested for water systems to "spring into" monitoring versus monitor to go to reduced/waivers. Work with the team to come up with your best professional judgement as to how many systems would be require to monitor for perchlorate by states. We'll need to come up with criteria for when we believe a state would require monitoring (e.g., water system is close to a facility that produces/uses perchlorate, has previous monitoring at levels close to the proposed MCL, uses hypochlorate, etc). Lisa Daniels of PA stated during NDWAC that she wouldn't offer any water systems who use hypochlorate to get a waiver, so we'll need to make some assumptions about how different states would implement. Some states by law cannot be more stringent than federal regulations, so we'll need to factor that in too. Once you've estimated the number of systems, we'll need to make assumptions about how initial, reduced and monitoring waivers will be implemented (maybe the same as proposed?). Also, we'll need a new cost/benefit estimate for this option. Please utilize your team members to help with this.
- ask Tom to research what is known about the levels of perchlorate in finished water due to hypochlorate use vs. perchlorate in source water.
-have other team members do some digging into SDWIS data to see if that helps inform this option.
-have a team member see if facilities that use/produce perchlorate can be identified to help estimate water systems within a certain proximity.

2. Assume all surface water systems will take 4 quarters of initial monitoring and all groundwater systems will take two quarters of initial monitoring and then if below the MCL will go directly to 9 year reduced monitoring (not a waiver). This cost/benefit estimate will also need to be done.

I'm out tomorrow and Monday, but would like to meet Tuesday to go over materials. The above options can be on a separate document for now. Eric wants a draft net week! We won't be able to get to option selection until we've explored Dave's suggestion and alternative 2 above.

If you have any questions, give me a call Ex. 6 Personal Privacy (PP)
I know this is a real challenge! Thanks,
Lisa

DRAFT -- INTERNAL DELIBERATIVE

All,
Attached is the current schedule for the tentative decision by Administrator Wheeler to withdraw the reg det. I've also attached the compendium of public comments. For the withdraw option, we can limit the scope of public comment topics we need to address. We are confirming this with OGC since our attorney has changed. We believe the topics we'll need to respond to include: withdrawing the reg det; the interim health advisory; health effects; and SDWA authority. I've highlighted the topics where we'll need OST support.

Subject: RE: FOR REVIEW: Perchlorate Reductions Over Time

Eric,
Attached is the document describing reductions in perchlorate since UCMR1. We worked with OPP on the labeling language and with OLEM on the list of superfund sites. Water systems that are being contacted by Abt are highlighted yellow. We're in the process of modifying the PWS recommendations and will have that ready for Jennifer soon.
Let us know if you have questions or concerns.

Lisa and team:
Thank you for the great work to prepare this document so quickly. It is a great. I do have a number of edits and comments but I believe we are heading in the right direction. Please look at my comments in the attached and let me know if you would like to discuss on Tuesday or Wednesday.
The next draft should get input from our Comms director which is why I have copied Christina so that she can start thinking about how she would like to present this information.

Thanks again for the great work.

Subject: RE: Revised Document

Hi Lisa,

We got new information from the MD system. There was some misunderstanding with the information request but here is the latest.

The treatment plant at chapel hill was recently taken off line and it was replaced with new productions wells and treatment plant which started operations in January 27, 2020. Please see the new language that I have incorporated in the revised document below.

"EPA contacted the Chapel Hill System in January 2020. Water system personnel indicated that the Chapel Hill WFP was taken off line and it was replaced with a new treatment plant and five new production wells. The new treatment plant started operations on January 27, 2020. System personnel also indicated that monitoring was conducted in November 2019 and the analysis shows that perchlorate was not detected in either the source well water or the finished water."

Thanks
Sam

Thanks Sam.
Do we know exactly what the contractor asked each PWS? Based on this response: **EPA contacted the Chapel Hill System in January 2020. Water system personnel indicated that no follow-up/updated monitoring data for perchlorate is available.** It appears we only asked about monitoring…did the contractor ask about any changes in source water and/or treatment too?

Thanks,
Lisa

Jennifer:

Attached for transmission to OW are revised versions of the FRN for the Perchlorate Final Action. There is both a clean and track changes version that includes edits made since initiating FAR (including the edits you asked for on Saturday and adding 3 more SAB recommendations to page 14 that were in the proposal but were not included in the draft we provided you on Friday). Also please find clean version of the transmittal memo from you to Dave Ross and the Action memo incorporating your edits.

Please note that there is also a redline version of the Action Memo for you to see the responses to your comments on the document. I do not recommend transmitting that memo to OW.

Sam

1. Change the title please. This was requested by OGC at Sr. Leadership levels.
2. Provide the same level of detail on the SAB recommendations as was included in the proposal.
3. I don't think the HRRCA text is necessary and do not want to add it at this stage since there are OGC edits that already make this clear.

Subject: RE: Notice of Final Action on Perchlorate

Hi Eric,

Here is a revised Redline of the document (from FAR). We had a few questions/issues for your consideration about the attached file. Specifically:,

1- Page #1, Notice Tittle: We did not accept the edits to the notice tittle. Because, the tittle of the notice was specifically crafted by OGC to capture the multiple actions EPA is taking. Suggest consulting with OGC before modifying this tittle.
2- Page #14, SAB Recommendations: SAB provided 4 main recommendations in 2013 but we only listed the first recommendation. Please advise if we should list all 4 recommendations here or not.
3- Page #26, Missing HRRCA Text: This language was offered by TAB in its 5-13-20 version of the draft FRN, but it did not show up in the version provided by OGWDW with Eric's & Jennifer's comments. We have inserted the language here for the reviewer's consideration. Please advise if we should keep it.

Once you provide your feedback, I will modify the redline version and also provide a Clean copy for transmittal.

Thanks
Sam

Jennifer

Attached for your approval and transmittal to the Office of Water for their approval and transmittal to the Office Policy for initiation of interagency review is a *Federal Register* notice titled: "Notice of Final Action on Perchlorate." Also attached for your review are a draft transmittal memo from you to the Assistant Administrator of Water, a draft Action Memorandum and a track changes version of the FR notice that denotes the changes made as a result of Final Agency Review.

On February 11, 2011, the EPA published a determination to regulate perchlorate in drinking water (76 FR 7762). On June 26, 2019 (84 FR 30524), the EPA published the proposed National Primary Drinking Water Regulation for Perchlorate and requested public comments on multiple alternative actions, including withdrawing the 2011 determination to regulate perchlorate. The EPA received approximately 1,500 comments on the proposed rule. In the attached notice, the EPA is withdrawing the 2011 Regulatory Determination and is making a final determination not to regulate perchlorate based on the Agency's consideration of public comments and the best available information.

I recommend that you approve and transmit the attached notice to the Office of Water for their review, approval and transmission to the Office of Policy to initiate interagency review in accordance with Executive Order 12866. If you need additional information or have questions pertaining to any aspect of this notice, please call me or have your staff contact Samuel Hernandez at 202-564-1735.

Christina:
Per our conversation, the attached is the perchlorate peer review report we intend to put into the docket. As discussed a brief desk statement indicating that we are reviewing the recommendations in the report and taking actions to improve the BBDR model is appropriate. We should also note that we intend to undertake peer review of a second document on methodologies to derive a perchlorate MCLG (using the BBDR model).

Eric- the peer review report is here and we are ready to post it to the docket. I wanted to check with you first to see if you wanted a briefing or summary of its contents?
There are no surprises in the report, it contains what we heard during the meeting - 1st trimester, TSH feedback, other giotrogens, more uncertainty analysis of key parameters. I've attached the report. If you're interested, in reading the executive summary it's a good representation of the report.

Jennifer:

Attached for transmission to OW are revised versions of the FRN for the Perchlorate Final Action. There is both a clean and track changes version that includes edits made since initiating FAR (including the edits you asked for on Saturday and adding 3 more SAB recommendations to page 14 that were in the proposal but were not included in the draft we provided you on Friday). Also please find clean version of the transmittal memo from you to Dave Ross and the Action memo incorporating your edits.

Please note that there is also a redline version of the Action Memo for you to see the responses to your comments on the document. I do not recommend transmitting that memo to OW.

Sam

1. Change the title please. This was requested by OGC at Sr. Leadership levels.
2. Provide the same level of detail on the SAB recommendations as was included in the proposal.
3. I don't think the HRRCA text is necessary and do not want to add it at this stage since there are OGC edits that already make this clear.

Subject: RE: Notice of Final Action on Perchlorate

Hi Eric,

Here is a revised Redline of the document (from FAR). We had a few questions/issues for your consideration about the attached file. Specifically:,

1- Page #1, Notice Tittle: We did not accept the edits to the notice tittle. Because, the tittle of the notice was specifically crafted by OGC to capture the multiple actions EPA is taking. Suggest consulting with OGC before modifying this tittle.
2- Page #14, SAB Recommendations: SAB provided 4 main recommendations in 2013 but we only listed the first recommendation. Please advise if we should list all 4 recommendations here or not.

3- Page #26, Missing HRRCA Text: This language was offered by TAB in its 5-13-20 version of the draft FRN, but it did not show up in the version provided by OGWDW with Eric's & Jennifer's comments. We have inserted the language here for the reviewer's consideration. Please advise if we should keep it.

Once you provide your feedback, I will modify the redline version and also provide a Clean copy for transmittal.

Thanks
Sam

Subject: Notice of Final Action on Perchlorate

Jennifer

Attached for your approval and transmittal to the Office of Water for their approval and transmittal to the Office Policy for initiation of interagency review is a *Federal Register* notice titled: "Notice of Final Action on Perchlorate." Also attached for your review are a draft transmittal memo from you to the Assistant

Administrator of Water, a draft Action Memorandum and a track changes version of the FR notice that denotes the changes made as a result of Final Agency Review.

On February 11, 2011, the EPA published a determination to regulate perchlorate in drinking water (76 FR 7762). On June 26, 2019 (84 FR 30524), the EPA published the proposed National Primary Drinking Water Regulation for Perchlorate and requested public comments on multiple alternative actions, including withdrawing the 2011 determination to regulate perchlorate. The EPA received approximately 1,500 comments on the proposed rule. In the attached notice, the EPA is withdrawing the 2011 Regulatory Determination and is making a final determination not to regulate perchlorate based on the Agency's consideration of public comments and the best available information.

I recommend that you approve and transmit the attached notice to the Office of Water for their review, approval and transmission to the Office of Policy to initiate interagency review in accordance with Executive Order 12866. If you need additional information or have questions pertaining to any aspect of this notice, please call me or have your staff contact Samuel Hernandez at 202-564-1735.

Attachments: Consolidated Perchlorate Draft Comment Response Report 4-24-20 v2.docx

Hi Sam,
I've attached the draft with my edits and comments. I want to consolidate responses so that if revisions are needed we don't need to cascade through the entire document. For example our ID#1.1 is essentially the same as #10.1. We should point all comments to #1.1, so I revised #10.1. I created a guide for myself to make sure things were pointing to 1 overarching response (see below). There needs to be a global search ID #1.1 not #1.1. Also make sure there are periods after See comment response ID #X.X. There were a few missing. This needs to be a really quick turnaround if you need help ask Jessica.
Lisa

Comment response ID

#1.1	**Ex. 5 Deliberative Process (DP)**

Subject: Response to comment document

Hi Lisa,

Attached you will find the consolidated response to comment document. To make the review process easier in this stage, I decided to have a separate file that includes only Section 8 (Health Effects). I think it is easier this way because it is the largest section in the document and providing edits and comments on the lager document might impact the editorial format on other sections.

I have only received partial input from ORD, I told Lynn that I could not wait any longer for their input and that I would send the document forward for review and that I was leaving placeholders for their input. There are only a handful of comments pending. She is aware of our very aggressive schedule on perchlorate.

I will be working in the coming days with the team to make another QA of the document to make sure that any issues we find are captured in the next round of revisions. I am also working on the cover and front matter of the report.

Thank You
Sam

Hi Lisa,

I am looking at these right now.

On a related note, I am having issues assessing my Perchlorate files on the Network. These reports from the occurrence analysis are in my network drive folders which I am unable to access. I will try again later tonight to see if lower network traffic lets me go in.

If I am unable to do so, I will have to go to the office to download my network drive to my Laptop, I will keep you posted.

Thanks
Sam

Hi Jennifer,

A few edits from Dave. Please review and confirm. In particular, please address the comment bubbles in the "Perchlorate Reductions" document. Please also review the write-up under #4 in the "Perchlorate Recommendations for PWS" document to confirm that it uses guidance type language, rather than authoritative, regulatory language. Due to formatting, yellow highlights (rather than redline) show changed text.

This is due tomorrow by noon, so please let me know as soon as the edits are incorporated.

Thank you,
Janita

Subject: Revised Perchlorate Briefing Documents

Jennifer:
Attached please find a revised Perchlorate Briefing documents. We had submitted a previous versions of these document for OW review along with the Perchlorate Reductions and Recommendations Documents. We have updated these documents while awaiting further comments from OW. The revisions made to the documents are as follows

- The one pager – Decision for Perchlorate Final Regulatory Action – Has been updated in response to Dave's request to incorporate information about the timing of the release of the stipulation to NRDC regarding the consent decree. This document reflects OGC's input.
- The Reductions Document – has been updated to reflect the information we received from the States of Maryland and Ohio regarding the status of the system that previously detected perchlorate at levels greater than 18ppb. We have also added a document number.
- The Recommendations Document has been updated to reflect add a Document Number.

If OW has not yet reviewed the last versions provided we recommend sending these forward to replace the versions awaiting review. If there are comments on the previous versions we can incorporate those prior to sending them forward.

Subject: RE: draft summary of perchlorate public comments

Thanks Lisa this breakdown is helpful but it pointed out to me that the 109 extensive and substantive letters don't all appear to be summarized.
I think there isn't a need to organize the commenters by organization type and there are some groups that are hard to categorize (i.e. we have ACWA as a regulated stakeholder but AWWA is a trade organization when the both represent drinking water utilities) I also think there is redundancy in the summary of the comments that I tried to eliminate in the attached.
Can the team take a look and see if there are organizations that have submitted extensive and substantive comments that we have not listed and if so please list them in the categories of support that are in the attached.

Sent: Tuesday, September 10, 2019 4:04 PM
To: Christ, Lisa <Christ.Lisa@epa.gov>
Subject: RE: draft summary of perchlorate public comments

Hi Lisa,

Here is a revised version which incorporates previously suggested edits.

- We received 6 comment letters in support of the proposed rule at 56 ppb.
- I cannot categorically confirm that the mass mailing campaign was organized by any group, so I am removing that designation from the summary document.
- From the individual substantive letters
    - 1 supports withdrawal option
    - 1 supports 90 ppb option
    - 6 support 18 ppb option
    - 23 support regulation at a stricter level than 18pbb

Thanks
Sam

To: Hernandez-Quinones, Samuel <Hernandez.Samuel@epa.gov>
Subject: FW: draft summary of perchlorate public comments

Hi Sam,
As follow up can you please:

- Confirm we did not get support for regulation at 56 ppb
- Confirm if NRDC is mentioned as the originator of the mass campaign
- Count the 88 individual comments that 1- support withdrawal, 2- support regulation (at any concentration).

Let me know if you have questions
Thanks,
Lisa

Subject: RE: draft summary of perchlorate public comments

Also There are three categories of commenters presented

1. Support withdrawal
2. Support a stricter than proposed standard
3. Neutral

Does this mean there were no commenters in support of the proposed MCLG/MCL?

Hi Sam,
Good morning. Attached are Jennifer's comments on the FRN which are pretty straight forward. I've also attached the action memo and response to comment section with my comments. Next steps:
Prepare revised FRN and memos for IO review and transmittal to Dave today.
Compile the RTC document so I can do a complete start-to-finish review for consistency, etc. We'll need to get this to Eric this week.

Thanks – let me know if you have questions or concerns.

Subject: RE: Let me know if you want me to call in for the meeting at 4PM

Hi Rajiv,
Sorry I didn't see this sooner! Eric suggested that we use different assumptions for the spring-in option. Rather than look at the state level, assume that all states will not require any monitoring for any system that had non-detect in UCMR1 and that any system with detects or that did not have data from UCMR1 (smalls) the state would make a case-by-case decision. Assume that the burden for the case-by-case system evaluation would be more burden hours than the waiver process. This can wait until you are back after the holidays.

Subject: Request for review - Draft Perchlorate Rule Proposal

Preliminary draft for internal EPA review

Hi,

Attached for your review is the Draft Perchlorate Rule Proposal (Preamble and Regulatory Text). As discussed previously we are asking that you provide your questions and or comments on the draft document to me by COB 2/15/2019. In order to keep with the consent decree deadline, we need to complete this step of the process within two weeks, if there are any issues that require technical discussions please let me know so that we can arrange any necessary working meeting.

I will follow-up with another email later today that contains the draft version of the technical support documents that were used as the basis for the Perchlorate proposal. Since those are very lengthy documents we are not requesting that you submit input and/or comments on those within the two- week time frame.

Please let me know if you have any questions.

Thanks
Sam

Subject: Perchlorate preamble draft

Sam,

Attached is the latest draft of the Perchlorate preamble. It has the following sections:

Health effects
Proposed MCLG
Occurrence
Treatment (BAT subsections may need more treatment detail especially any limitations to use)
Economic analysis methods and results (the benefits section needs more detail; I am wondering if we should include the equations?)
Executive Orders (there are highlights on text about things I don't know like outreach/consultation and gray highlights on values that may change).

Hope you will find this useful. Thanks

Rajiv
